Summary

MATLAB routines

Multirate systems include more than one sample rate

Why bother?:

- May need to **change the sample rate**
e.g. Audio sample rates include 32, 44.1, 48, 96 kHz
- Can **relax** analog or digital **filter requirements**
e.g. Audio DAC increases sample rate so that the reconstruction filter can have a more gradual cutoff
- **Reduce computational complexity**
FIR filter length $\propto \frac{f_s}{\Delta f}$ where Δf is width of transition band
Lower $f_s \Rightarrow$ shorter filter + fewer samples \Rightarrow computation $\propto f_s^2$

Summary

MATLAB routines

Downsample $x[n] \xrightarrow{K:1} y[m] \quad y[m] = x[Km]$

Upsample $u[m] \xrightarrow{1:K} v[n] \quad v[n] = \begin{cases} u\left[\frac{n}{K}\right] & K \mid n \\ 0 & \text{else} \end{cases}$

Example:

Downsample by 3 then upsample by 4

- We use different index variables (n , m , r) for different sample rates
- Use different colours for signals at different rates (sometimes)
- **Synchronization:** all signals have a sample at $n = 0$.

Commutators

Summary

MATLAB routines

Successive downsamplers or up-samplers can be combined

Upsampling can be exactly inverted

Downsampling **destroys information permanently** \Rightarrow uninvertible

Resampling can be interchanged **iff P and Q are coprime** (surprising!)

Proof: Left side: $y[n] = w \left[\frac{1}{Q}n \right] = x \left[\frac{P}{Q}n \right]$ if $Q \mid n$ else $y[n] = 0$.

Right side: $v[n] = u [Pn] = x \left[\frac{P}{Q}n \right]$ if $Q \mid Pn$.

But $\{Q \mid Pn \Rightarrow Q \mid n\}$ iff P and Q are coprime.

[Note: $a \mid b$ means “ a divides into b exactly”]

Summary

MATLAB routines

Define $h_Q[n]$ to be the impulse response of $H(z^Q)$.

$$\boxed{x[n]} \boxed{Q:1} \boxed{u[r]} \boxed{H(z)} \boxed{y[r]} = \boxed{x[n]} \boxed{H(z^Q)} \boxed{v[n]} \boxed{Q:1} \boxed{w[r]}$$

Assume that $h[r]$ is of length $M + 1$ so that $h_Q[n]$ is of length $QM + 1$. We know that $h_Q[n] = 0$ except when $Q \mid n$ and that $h[r] = h_Q[Qr]$.

$$\begin{aligned} w[r] &= v[Qr] = \sum_{s=0}^{QM} h_Q[s]x[Qr - s] \\ &= \sum_{m=0}^M h_Q[Qm]x[Qr - Qm] = \sum_{m=0}^M h[m]x[Q(r - m)] \\ &= \sum_{m=0}^M h[m]u[r - m] = y[r] \end{aligned}$$

Upsampled Noble Identity:

$$\boxed{x[r]} \boxed{H(z)} \boxed{u[r]} \boxed{1:Q} \boxed{y[n]} = \boxed{x[r]} \boxed{1:Q} \boxed{v[n]} \boxed{H(z^Q)} \boxed{w[n]}$$

We know that $v[n] = 0$ except when $Q \mid n$ and that $v[Qr] = x[r]$.

$$\begin{aligned} w[n] &= \sum_{s=0}^{QM} h_Q[s]v[n - s] = \sum_{m=0}^M h_Q[Qm]v[n - Qm] \\ &= \sum_{m=0}^M h[m]v[n - Qm] \end{aligned}$$

If $Q \nmid n$, then $v[n - Qm] = 0 \forall m$ so $w[n] = 0 = y[n]$

$$\begin{aligned} \text{If } Q \mid n = Qr, \text{ then } w[Qr] &= \sum_{m=0}^M h[m]v[Qr - Qm] \\ &= \sum_{m=0}^M h[m]x[r - m] = u[r] = y[Qr] \end{aligned}$$

Summary

MATLAB routines

$$\begin{aligned}
 V(z) &= \sum_n v[n] z^{-n} = \sum_{n \text{ s.t. } K|n} u\left[\frac{n}{K}\right] z^{-n} \\
 &= \sum_m u[m] z^{-Km} = U(z^K)
 \end{aligned}$$

$$\underline{u[m]} \boxed{1:K} \underline{v[n]}$$

$$\underline{U(z)} \boxed{1:K} \underline{U(z^K)}$$

Spectrum: $V(e^{j\omega}) = U(e^{jK\omega})$

Spectrum is horizontally shrunk and replicated K times.

Total **energy** unchanged; **power** (= energy/sample) multiplied by $\frac{1}{K}$

Upsampling normally **followed** by a LP filter to remove images.

Example:

$K = 3$: three images of the original spectrum in all.

Energy unchanged: $\frac{1}{2\pi} \int |U(e^{j\omega})|^2 d\omega = \frac{1}{2\pi} \int |V(e^{j\omega})|^2 d\omega$

Summary

MATLAB routines

Define $c_K[n] = \delta_{K|n}[n] = \frac{1}{K} \sum_{k=0}^{K-1} e^{\frac{j2\pi kn}{K}}$ $x[n] \boxed{K:1} y[m] \boxed{1:K} x_K[n]$

Now define $x_K[n] = \begin{cases} x[n] & K | n \\ 0 & K \nmid n \end{cases} = c_K[n]x[n]$

$$\begin{aligned} X_K(z) &= \sum_n x_K[n]z^{-n} = \frac{1}{K} \sum_n \sum_{k=0}^{K-1} e^{\frac{j2\pi kn}{K}} x[n]z^{-n} \\ &= \frac{1}{K} \sum_{k=0}^{K-1} \sum_n x[n] \left(e^{\frac{-j2\pi k}{K}} z \right)^{-n} = \frac{1}{K} \sum_{k=0}^{K-1} X(e^{\frac{-j2\pi k}{K}} z) \end{aligned}$$

From previous slide:

$$X(z) \boxed{K:1} \frac{1}{K} \sum_{k=0}^{K-1} X(e^{\frac{-j2\pi k}{K}} z^{\frac{1}{K}})$$

$$X_K(z) = Y(z^K)$$

$$\Rightarrow Y(z) = X_K(z^{\frac{1}{K}}) = \frac{1}{K} \sum_{k=0}^{K-1} X(e^{\frac{-j2\pi k}{K}} z^{\frac{1}{K}})$$

Frequency Spectrum:

$$\begin{aligned} Y(e^{j\omega}) &= \frac{1}{K} \sum_{k=0}^{K-1} X(e^{\frac{j(\omega-2\pi k)}{K}}) \\ &= \frac{1}{K} \left(X(e^{\frac{j\omega}{K}}) + X(e^{\frac{j\omega}{K} - \frac{2\pi}{K}}) + X(e^{\frac{j\omega}{K} - \frac{4\pi}{K}}) + \dots \right) \end{aligned}$$

Average of K aliased versions, each expanded in ω by a factor of K .

Downsampling is normally **preceded** by a LP filter to prevent aliasing.

Summary

MATLAB routines

$$Y(e^{j\omega}) = \frac{1}{K} \sum_{k=0}^{K-1} X(e^{j(\omega - 2\pi k)/K})$$

$$x[n] \xrightarrow{K:1} y[m]$$

Example 1:

$$K = 3$$

Not quite limited to $\pm \frac{\pi}{K}$

Shaded region shows aliasing

Energy decreases: $\frac{1}{2\pi} \int |Y(e^{j\omega})|^2 d\omega \approx \frac{1}{K} \times \frac{1}{2\pi} \int |X(e^{j\omega})|^2 d\omega$

Example 2:

$$K = 3$$

Energy all in $\frac{\pi}{K} \leq |\omega| < 2\frac{\pi}{K}$

No aliasing: 😊

No aliasing: If all energy is in $r\frac{\pi}{K} \leq |\omega| < (r+1)\frac{\pi}{K}$ for some integer r

Normal case ($r = 0$): If all energy in $0 \leq |\omega| \leq \frac{\pi}{K}$

Downsampling: Total **energy** multiplied by $\approx \frac{1}{K}$ ($= \frac{1}{K}$ if no aliasing)

Average **power** \approx unchanged ($=$ energy/sample)

Summary

MATLAB routines

Example: Signal in $\omega \in \pm 0.4\pi$ + Tone @ $\omega = \pm 0.1\pi$ + White noise

Power = Energy/sample = Average PSD

$$= \frac{1}{2\pi} \int_{-\pi}^{\pi} \text{PSD}(\omega) d\omega = 0.6$$

Component powers:

Signal = 0.3, Tone = 0.2, Noise = 0.1

Upsampling:

Same energy
per second

⇒ Power is $\div K$

Downsampling:

Average power
is unchanged.

∃ aliasing in
the $\div 3$ case.

[Power Spectral Density (1)]

The energy of a spectrum is $E_x = \sum_{-\infty}^{+\infty} |x[n]|^2$ and its power is $P_x = \lim_{N \rightarrow \infty} \frac{1}{2N+1} \sum_{-N}^{+N} |x[n]|^2$. The energy, E_x , is the total energy in all samples while the power, P_x , is the average energy per

sample. If the finite signal $x_N[n]$ is defined as $x_N[n] = \begin{cases} x[n] & |n| \leq N \\ 0 & |n| > N \end{cases}$, then the power spectral

density (PSD) is given by $S_{xx}(e^{j\omega}) = \lim_{N \rightarrow \infty} \frac{1}{2N+1} |X_N(e^{j\omega})|^2$. From Parseval's theorem, P_x is the average value of $S_{xx}(e^{j\omega})$ or, equivalently, $P_x = \frac{1}{2\pi} \int_{-\pi}^{\pi} S_{xx}(e^{j\omega}) d\omega$.

The signal on the previous slide has three components: (i) a signal component with a power of 0.3 and a trapezoidal PSD with a width of $\pm 0.4\pi$, (ii) a tonal component with a power of 0.2 whose PSD consists of two delta functions and (iii) a white noise component of power 0.1 whose PSD is constant at 0.1. The tonal component might arise from a time-domain waveform $\sqrt{0.4} \cos(0.1\pi n + \phi)$ where ϕ is arbitrary and does not affect the PSD.

Upsampling by K inserts additional zero-valued samples and so does not affect E_x but, since there are now K times as many samples, P_x is divided by K . The original periodic PSD is shrunk horizontally by a factor of K which means that there are now K images of the original PSD at spacings of $\Delta\omega = \frac{2\pi}{K}$. So, for example, when $K = 2$, the central trapezoidal component has a maximum height of 0.5 and a width of $\pm 0.2\pi$ and there is a second, identical, trapezoidal component shifted by $\Delta\omega = \frac{2\pi}{K} = \pi$. When K is an even number, one of the images will be centred on $\omega = \pi$ and so will wrap around from $+\pi$ to $-\pi$. The power of each image is multiplied by K^{-2} but, since there are K images, the total power is multiplied by K^{-1} . For the white noise, the images all overlap (and add in power), so the white noise PSD amplitude is multiplied by K^{-1} . Finally, the amplitudes of the delta functions are multiplied by K^{-2} so that the total power of all K images is multiplied by K^{-1} .

[Power Spectral Density (2)]

Downsampling by K deletes samples but leaves the average power of the remaining ones unchanged. Thus the total power of the downsampled spectra remains at 0.6. The downsampled PSD is the average of K shifted versions of the original PSD that have been expanded horizontally by a factor of K . The white noise component is the average of K identical expanded but attenuated versions of itself and so its PSD amplitude remains at 0.1. The power of a tonal components is unchanged and so its amplitude is also unchanged.

When downsampling by a factor of $K = 3$, the original width of the trapezoidal component expands from $\pm 0.4\pi$ to $\pm 1.2\pi$ which exceeds the $\pm\pi$ range of the graph. Thus, as ω approaches π , the PSD of the signal component is decreasing with ω but has not reached 0 at $\omega = \pi$. This portion of the trapezium wraps around to $\omega = -\pi$ and gives rise to the little triangle of additional noise in the range $-\pi < \omega < -0.8\pi$ where it adds onto the white noise component. In a similar way, the portion of the trapezium that overflows the left edge of the graph gives rise to additional noise at the right of the graph in the range $0.8\pi < \omega < \pi$.

Summary of Spectral Density Changes: Width \times Height (\times Images)

Energy and Power Spectral Densities	Energy Spectral Density		Power Spectral Density	
	Up: $1 : K$	Down: $K : 1$	Up: $1 : K$	Down: $K : 1$
Alias-free block	$K^{-1} \times 1 (\times K)$	$K \times K^{-2}$	$K^{-1} \times K^{-1} (\times K)$	$K \times K^{-1}$
Tone: $\delta(\omega - \omega_0)$	$1 \times K^{-1} (\times K)$	$1 \times K^{-1}$	$1 \times K^{-2} (\times K)$	1×1
White Noise	1×1	$1 \times K^{-1}$	$1 \times K^{-1}$	1×1
Integral $\int d\omega$	$\times 1$	$\approx \times K^{-1}$	$\times K^{-1}$	$\approx \times 1$

Summary

MATLAB routines

$x[n]$	c d e f g h i j k l m n
$u[m]$	c f i l
$p[n]$	-c--f--i--l
$v[m]$	b e h k
$q[n]$	-bc-ef-hi-kl
$w[m]$	a d g j
$y[n]$	a b c d e f g h i j k l

Input sequence $x[n]$ is split into three streams at $\frac{1}{3}$ the sample rate:

$$u[m] = x[3m], \quad v[m] = x[3m - 1], \quad w[m] = x[3m - 2]$$

Following upsampling, the streams are aligned by the delays and then added to give:

$$y[n] = x[n - 2]$$

Perfect Reconstruction: output is a delayed scaled replica of the input

Summary

MATLAB routines

$x[n]$	c	d	e	f	g	h	i	j	k	l	m	n
$u[m]$				c			f			i		l
$v[m]$				b			e			h		k
$w[m]$				a			d			g		j
$v[m + \frac{1}{3}]$							e			h		k
$w[m + \frac{2}{3}]$							d			g		j
$y[n]$	a	b	c	d	e	f	g	h	i	j	k	l

The combination of delays and downsamplers can be regarded as a **commutator** that **distributes values in sequence** to u , w and v . Fractional delays, $z^{-\frac{1}{3}}$ and $z^{-\frac{2}{3}}$ are needed to synchronize the streams. The **output commutator** takes values from the streams in sequence. For clarity, we omit the fractional delays and regard each terminal, \circ , as holding its value until needed. **Initial commutator position has zero delay.**

The commutator direction is **against the direction** of the z^{-1} delays.
