- Power and Energy
- Summary

A capacitor is formed from two conducting plates separated by a thin insulating layer.

If a current $i$ flows, positive change, $q$, will accumulate on the upper plate. To preserve charge neutrality, a balancing negative charge will be present on the lower plate.

- Summary

A capacitor is formed from two conducting plates separated by a thin insulating layer.

If a current $i$ flows, positive change, $q$, will accumulate on the upper plate. To preserve charge neutrality, a balancing negative charge will be present on the lower plate.

There will be a potential energy difference (or voltage $v$ ) between the plates proportional to $q$.
$v=\frac{d}{A \epsilon} q$ where $A$ is the area of the plates, $d$ is their separation and $\epsilon$ is the permittivity of the insulating layer ( $\epsilon_{0}=8.85 p F / \mathrm{m}$ for a vacuum).

- Inductors
- Passive Components
- Series and Parallel

Inductors

- Series and Parallel

Capacitors

- Current/Voltage Continuity
- Average Current/Voltage
- Buck Converter
- Power and Energy
- Summary

Inductors are formed from coils of wire, often around a steel or ferrite core.

The magnetic flux within the coil is $\Phi=\frac{\mu N A}{l} i$ where $N$ is the number of turns, $A$ is the cross-sectional area of the coil and $l$ is the length of the coil (around the toroid).
$\mu$ is a property of the material that the core is made from and is called its permeability. For free space (or air): $\mu_{0}=4 \pi \times 10^{-7}=1.26 \mu \mathrm{H} / \mathrm{m}$, for steel, $\mu \approx 4000 \mu_{0}=5 \mathrm{mH} / \mathrm{m}$.

- Summary

Inductors are formed from coils of wire, often around a steel or ferrite core.

The magnetic flux within the coil is $\Phi=\frac{\mu N A}{l} i$ where $N$ is the number of turns, $A$ is the cross-sectional area of the coil and $l$ is the length of the coil (around the toroid).
$\mu$ is a property of the material that the core is made from and is called its permeability. For free space (or air): $\mu_{0}=4 \pi \times 10^{-7}=1.26 \mu \mathrm{H} / \mathrm{m}$, for steel, $\mu \approx 4000 \mu_{0}=5 \mathrm{mH} / \mathrm{m}$.

From Faraday's law: $v=N \frac{d \Phi}{d t}=\frac{\mu N^{2} A}{l} \frac{d i}{d t}=L \frac{d i}{d t}$.
We measure the inductance, $L=\frac{\mu N^{2} A}{l}$, in Henrys (H).

## Passive Components

=\frac{C}{t_{2}-t_{1}}[v]_{v\left(t_{1}\right)}^{v\left(t_{2}\right)}=\frac{C}{t_{2}-t_{1}}\left(v\left(t_{2}\right)-v\left(t_{1}\right)\right)
\end{gathered}
$$

(1) If $v\left(t_{1}\right)=v\left(t_{2}\right)$ then the average current exactly equals zero.
(2) If $v$ is bounded then the average current $\rightarrow 0$ as $\left(t_{2}-t_{1}\right) \rightarrow \infty$.

The average current through a capacitor is zero and, likewise, the average voltage across an inductor is zero. The circuit symbols remind you of this.
"Average" can either be over an exact number of periods of a repetitive waveform or else the long-term average (provided $v$ and $i$ remain bounded).
" $v$ is bounded" means $|v|$ always stays less than a predefined maximum value.

- Summary

A buck converter converts a high voltage, $V$, into a lower one, $Y$.

The switch, $S$, closes for a fraction $a$ of the time. $a$ is the duty cycle and is $\frac{1}{3}$ in this example.
When $S$ is closed, $x=v$, and a current $i_{L}$ flows.
When $S$ opens, the current $i_{L}$ cannot change instantly and so it must flow through the diode (we assume the diode is ideal).

The average value of $x$ is $a V \Rightarrow$ the average value of $y$ must also be $a V$.
The average current through $R$ is $\frac{a V}{R}$ so, since the average current through $C$ must be zero, the average current $i_{L}$ must also be $\frac{a V}{R}$.
$C \frac{d y}{d t}=i_{L}-i_{R} \Rightarrow$ if $C$ is large, then the variations in $y$ will be very small.

## Buck Converter

- Average Current/Voltage
- Buck Converter
- Power and Energy
- Summary
[Do not memorize this circuit]
A buck converter converts a high voltage, $V$, into a lower one, $Y$.

The switch, $S$, closes for a fraction $a$ of the time. $a$ is the duty cycle and is $\frac{1}{3}$ in this example.
When $S$ is closed, $x=v$, and a current $i_{L}$ flows.
When $S$ opens, the current $i_{L}$ cannot change instantly and so it must flow through the diode (we assume the diode is ideal).

The average value of $x$ is $a V \Rightarrow$ the average value of $y$ must also be $a V$.
The average current through $R$ is $\frac{a V}{R}$ so, since the average current through $C$ must be zero, the average current $i_{L}$ must also be $\frac{a V}{R}$.
$C \frac{d y}{d t}=i_{L}-i_{R} \Rightarrow$ if $C$ is large, then the variations in $y$ will be very small.
