# Claude Shannon

---

- “The fundamental problem of communication is that of reproducing at one point either exactly or approximately a message selected at another point.” (Claude Shannon 1948)

- Channel Coding Theorem:

It is possible to achieve near perfect communication of information over a noisy channel

- In this course we will:
  - Define what we mean by information
  - Show how we can compress the information in a source to its theoretically minimum value and show the tradeoff between data compression and distortion.
  - Prove the Channel Coding Theorem and derive the information capacity of different channels.

1916 - 2001

# Textbooks

---

Book of the course:

- *Elements of Information Theory* by T M Cover & J A Thomas, Wiley 2006, 978-0471241959 £30 (Amazon)

Alternative book – a denser but entertaining read that covers most of the course + much else:

- *Information Theory, Inference, and Learning Algorithms*, D MacKay, CUP, 0521642981 £28 or free at <http://www.inference.phy.cam.ac.uk/mackay/itila/>

Assessment: Exam only – no coursework.

Acknowledgement: Many of the examples and proofs in these notes are taken from the course textbook “Elements of Information Theory” by T M Cover & J A Thomas and/or the lecture notes by Dr L Zheng based on the book.

# Notation

---

- Vectors and Matrices
  - $\mathbf{v}$ =vector,  $\mathbf{V}$ =matrix,  $\odot$ =elementwise product
- Scalar Random Variables
  - $X$  = R.V,  $x$  = specific value,  $\mathcal{X}$  = alphabet
- Random Column Vector of length  $N$ 
  - $\mathbf{x}$ = R.V,  $\mathbf{x}$  = specific value,  $\mathcal{X}^N$  = alphabet
  - $x_i$  and  $x_i$  are particular vector elements
- Ranges
  - $a:b$  denotes the range  $a, a+1, \dots, b$

# Discrete Random Variables

---

- A random variable  $x$  takes a value  $x$  from the alphabet  $\mathcal{X}$  with probability  $p_x(x)$ . The vector of probabilities is  $\mathbf{p}_x$ .

Examples:

$$\mathcal{X} = [1; 2; 3; 4; 5; 6], \mathbf{p}_x = [1/6; 1/6; 1/6; 1/6; 1/6; 1/6]$$

$\mathbf{p}_x$  is a “probability mass vector”

“english text”

$$\mathcal{X} = [a; b; \dots, y; z; \text{<space>}]$$

$$\mathbf{p}_x = [0.058; 0.013; \dots; 0.016; 0.0007; 0.193]$$

Note: we normally drop the subscript from  $p_x$  if unambiguous

# Expected Values

---

- If  $g(x)$  is real valued and defined on  $\mathcal{X}$  then

$$E_{\mathcal{X}} g(\mathcal{X}) = \sum_{x \in \mathcal{X}} p(x)g(x) \quad \text{often write } E \text{ for } E_{\mathcal{X}}$$

Examples:

$$\mathcal{X} = [1;2;3;4;5;6], \mathbf{p}_{\mathcal{X}} = [1/6; 1/6; 1/6; 1/6; 1/6; 1/6]$$

$$E \mathcal{X} = 3.5 = \mu$$

$$E \mathcal{X}^2 = 15.17 = \sigma^2 + \mu^2$$

$$E \sin(0.1\mathcal{X}) = 0.338$$

$$E -\log_2(p(\mathcal{X})) = 2.58 \quad \longleftarrow \text{This is the "entropy" of } \mathcal{X}$$

# Shannon Information Content

---

- The **Shannon Information Content** of an outcome with probability  $p$  is  $-\log_2 p$
- Example 1: Coin tossing
  - $\mathbf{X} = [\text{Heads}; \text{Tails}]$ ,  $\mathbf{p} = [1/2; 1/2]$ , SIC = [1; 1] bits
- Example 2: Is it my birthday ?
  - $\mathbf{X} = [\text{No}; \text{Yes}]$ ,  $\mathbf{p} = [364/365; 1/365]$ ,  
SIC = [0.004; 8.512] bits

Unlikely outcomes give more information

# Minesweeper

---

- Where is the bomb ?
- 16 possibilities – needs 4 bits to specify

| Guess | Prob            | SIC        |
|-------|-----------------|------------|
| 1. No | $\frac{15}{16}$ | 0.093 bits |

# Entropy

---

The **entropy**,  $H(X) = E - \log_2(p_X(X)) = -\mathbf{p}_X^T \log_2 \mathbf{p}_X$

- $H(x)$  = the average Shannon Information Content of  $x$
- $H(x)$  = the average information gained by knowing its value
- the average number of “yes-no” questions needed to find  $x$  is in the range  $[H(x), H(x)+1)$

We use  $\log(x) \equiv \log_2(x)$  and measure  $H(x)$  in **bits**

- if you use  $\log_e$  it is measured in **nats**
- 1 nat =  $\log_2(e)$  bits = 1.44 bits

$$\bullet \quad \log_2(x) = \frac{\ln(x)}{\ln(2)} \qquad \frac{d \log_2 x}{dx} = \frac{\log_2 e}{x}$$

$H(X)$  depends only on the probability vector  $\mathbf{p}_X$  not on the alphabet  $\mathcal{X}$ ,  
so we can write  $H(\mathbf{p}_X)$

# Entropy Examples

## (1) Bernoulli Random Variable

$$\mathcal{X} = [0; 1], \mathbf{p}_x = [1-p; p]$$

$$H(x) = -(1-p)\log(1-p) - p\log p$$

Very common – we write  $H(p)$  to mean  $H([1-p; p])$ .

## (2) Four Coloured Shapes

$$\mathcal{X} = [\text{red circle}; \text{green square}; \text{blue diamond}; \text{black flower}], \mathbf{p}_x = [1/2; 1/4; 1/8; 1/8]$$

$$\begin{aligned} H(x) &= H(\mathbf{p}_x) = \sum -\log(p(x))p(x) \\ &= 1 \times 1/2 + 2 \times 1/4 + 3 \times 1/8 + 3 \times 1/8 = 1.75 \text{ bits} \end{aligned}$$

# Bernoulli Entropy Properties

$$\mathcal{X} = [0;1], \mathbf{p}_x = [1-p; p]$$

$$H(p) = -(1-p)\log(1-p) - p\log p$$

$$H'(p) = \log(1-p) - \log p$$

$$H''(p) = -p^{-1}(1-p)^{-1} \log e$$

## Quadratic Bounds

$$H(p) \leq 1 - 2\log e (p - \tfrac{1}{2})^2$$

$$= 1 - 2.89(p - \tfrac{1}{2})^2$$

$$H(p) \geq 1 - 4(p - \tfrac{1}{2})^2$$

$$\geq 2\min(p, 1-p)$$

Proofs in problem sheet

# Joint and Conditional Entropy

## Joint Entropy: $H(X, Y)$

$$H(X, Y) = E - \log p(X, Y)$$

$$= -\frac{1}{2} \log \frac{1}{2} - \frac{1}{4} \log \frac{1}{4} - 0 \log 0 - \frac{1}{4} \log \frac{1}{4} = 1.5 \text{ bits}$$

Note:  $0 \log 0 = 0$

| $p(X, Y)$ | $Y=0$         | $Y=1$         |
|-----------|---------------|---------------|
| $X=0$     | $\frac{1}{2}$ | $\frac{1}{4}$ |
| $X=1$     | 0             | $\frac{1}{4}$ |

## Conditional Entropy : $H(Y | X)$

$$H(Y | X) = E - \log p(Y | X)$$

$$= -\frac{1}{2} \log \frac{2}{3} - \frac{1}{4} \log \frac{1}{3} - 0 \log 0 - \frac{1}{4} \log 1 = 0.689 \text{ bits}$$

Note: rows sum to 1

| $p(Y X)$ | $Y=0$         | $Y=1$         |
|----------|---------------|---------------|
| $X=0$    | $\frac{2}{3}$ | $\frac{1}{3}$ |
| $X=1$    | 0             | 1             |

# Conditional Entropy – view 1

## Additional Entropy:

$$p(y | x) = p(x, y) \div p(x)$$

$$H(y | x) = E - \log p(y | x)$$

$$= E \{-\log p(x, y)\} - E \{-\log p(x)\}$$

$$= H(x, y) - H(x) = H(1/2, 1/4, 0, 1/4) - H(1/4) = 0.689 \text{ bits}$$

| $p(x, y)$ | $y=0$ | $y=1$ | $p(x)$ |
|-----------|-------|-------|--------|
| $x=0$     | $1/2$ | $1/4$ | $3/4$  |
| $x=1$     | $0$   | $1/4$ | $1/4$  |

$H(Y|X)$  is the average additional information in  $Y$  when you know  $X$

# Conditional Entropy – view 2

Average Row Entropy:

| $p(x, y)$ | $y=0$ | $y=1$ | $H(y   x=x)$ | $p(x)$ |
|-----------|-------|-------|--------------|--------|
| $x=0$     | $1/2$ | $1/4$ | $H(1/3)$     | $3/4$  |
| $x=1$     | $0$   | $1/4$ | $H(1)$       | $1/4$  |

$$\begin{aligned}
 H(y | x) &= E - \log p(y | x) = \sum_{x,y} -p(x,y) \log p(y | x) \\
 &= \sum_{x,y} -p(x)p(y | x) \log p(y | x) = \sum_{x \in \mathcal{X}} p(x) \sum_{y \in \mathcal{Y}} -p(y | x) \log p(y | x) \\
 &= \sum_{x \in \mathcal{X}} p(x) H(y | x = x) = \frac{3}{4} \times H(\frac{1}{3}) + \frac{1}{4} \times H(0) = 0.689 \text{ bits}
 \end{aligned}$$

Take a weighted average of the entropy of each row using  $p(x)$  as weight

# Chain Rules

---

- Probabilities

$$p(x, y, z) = p(z \mid x, y)p(y \mid x)p(x)$$

- Entropy

$$H(x, y, z) = H(z \mid x, y) + H(y \mid x) + H(x)$$

$$H(x_{1:n}) = \sum_{i=1}^n H(x_i \mid x_{1:i-1})$$

The log in the definition of entropy converts products of probability into sums of entropy

# Summary

- **Entropy:**  $H(X) = \sum_{x \in \mathcal{X}} -\log_2(p(x))p(x) = E - \log_2(p_X(x))$ 
  - Bounded  $0 \leq H(X) \leq \log |\mathcal{X}|$

- **Chain Rule:**

$$H(X, Y) = H(Y | X) + H(X)$$

- **Conditional Entropy:**

$$H(Y | X) = H(X, Y) - H(X) = \sum_{x \in \mathcal{X}} p(x)H(Y | x)$$

- Conditioning reduces entropy  $H(Y | X) \leq H(Y)$

◆ = inequalities not yet proved

# Lecture 2

---

- Mutual Information
  - If  $x$  and  $y$  are correlated, their mutual information is the average information that  $y$  gives about  $x$ 
    - E.g. Communication Channel:  $x$  transmitted but  $y$  received
- Jensen's Inequality
- Relative Entropy
  - Is a measure of how different two probability mass vectors are
- Information Inequality and its consequences
  - Relative Entropy is always positive
    - Mutual information is positive
    - Uniform bound
    - Conditioning and Correlation reduce entropy

# Mutual Information

The **mutual information** is the average amount of information that you get about  $x$  from observing the value of  $y$

$$I(x; y) = H(x) - H(x | y) = H(x) + H(y) - H(x, y)$$

Information in  $x$

Information in  $x$  when you already know  $y$

Mutual information is **symmetrical**

$$I(x; y) = I(y; x)$$

Use “;” to avoid ambiguities between  $I(x; y, z)$  and  $I(x, y; z)$

# Mutual Information Example

| $p(x,y)$ | $y=0$ | $y=1$ |
|----------|-------|-------|
| $x=0$    | $1/2$ | $1/4$ |
| $x=1$    | 0     | $1/4$ |

- If you try to guess  $y$  you have a 50% chance of being correct.
- However, what if you know  $x$ ?
  - Best guess: choose  $y = x$
  - If  $x=0$  ( $p=0.75$ ) then 66% correct prob
  - If  $x=1$  ( $p=0.25$ ) then 100% correct prob
  - Overall 75% correct probability

$$I(x;y) = H(x) - H(x|y)$$

$$= H(x) + H(y) - H(x,y)$$

$$H(x) = 0.811, \quad H(y) = 1, \quad H(x,y) = 1.5$$

$$I(x;y) = 0.311$$

# Conditional Mutual Information

---

## Conditional Mutual Information

$$\begin{aligned} I(x; y | z) &= H(x | z) - H(x | y, z) \\ &= H(x | z) + H(y | z) - H(x, y | z) \end{aligned}$$

**Note:**  $Z$  conditioning applies to both  $X$  and  $Y$

## Chain Rule for Mutual Information

$$I(x_1, x_2, x_3; y) = I(x_1; y) + I(x_2; y | x_1) + I(x_3; y | x_1, x_2)$$

$$I(x_{1:n}; y) = \sum_{i=1}^n I(x_i; y | x_{1:i-1})$$

# Review/Preview

- **Entropy:**  $H(x) = \sum_{x \in \mathcal{X}} -\log_2(p(x))p(x) = E - \log_2(p_X(x))$ 
  - Always positive  $H(x) \geq 0$
- **Chain Rule:**  $H(x, y) = H(x) + H(y | x) \leq H(x) + H(y)$  ♦
  - Conditioning reduces entropy  $H(y | x) \leq H(y)$  ♦
- **Mutual Information:**

$$I(y; x) = H(y) - H(y | x) = H(x) + H(y) - H(x, y)$$
  - Positive and Symmetrical  $I(x; y) = I(y; x) \geq 0$  ♦
  - $x$  and  $y$  independent  $\Leftrightarrow H(x, y) = H(y) + H(x)$  ♦
 
$$\Leftrightarrow I(x; y) = 0$$

♦ = inequalities not yet proved

# Convex & Concave functions

$f(x)$  is **strictly convex** over  $(a,b)$  if

$$f(\lambda u + (1-\lambda)v) < \lambda f(u) + (1-\lambda)f(v) \quad \forall u \neq v \in (a,b), 0 < \lambda < 1$$

- every chord of  $f(x)$  lies above  $f(x)$
- $f(x)$  is **concave**  $\Leftrightarrow -f(x)$  is **convex**

- **Examples**

- Strictly Convex:  $x^2, x^4, e^x, x \log x [x \geq 0]$
- Strictly Concave:  $\log x, \sqrt{x} [x \geq 0]$
- Convex and Concave:  $x$

- Test:  $\frac{d^2 f}{dx^2} > 0 \quad \forall x \in (a,b) \quad \Rightarrow f(x) \text{ is strictly convex}$

Concave is like this

“**convex**” (not strictly) uses “ $\leq$ ” in definition and “ $\geq$ ” in test

# Jensen's Inequality

**Jensen's Inequality:** (a)  $f(x)$  convex  $\Rightarrow E f(X) \geq f(E X)$

(b)  $f(x)$  strictly convex  $\Rightarrow E f(X) > f(E X)$  unless  $x$  constant

Proof by induction on  $|X|$

–  $|X|=1$ :  $E f(X) = f(E X) = f(x_1)$

–  $|X|=k$ :  $E f(X) = \sum_{i=1}^k p_i f(x_i) = p_k f(x_k) + (1 - p_k) \sum_{i=1}^{k-1} \frac{p_i}{1 - p_k} f(x_i)$

These sum to 1

$$\geq p_k f(x_k) + (1 - p_k) f\left(\sum_{i=1}^{k-1} \frac{p_i}{1 - p_k} x_i\right)$$

Assume JI is true for  $|X|=k-1$

$$\geq f\left(p_k x_k + (1 - p_k) \sum_{i=1}^{k-1} \frac{p_i}{1 - p_k} x_i\right) = f(E X)$$

Can replace by “>” if  $f(x)$  is strictly convex unless  $p_k \in \{0, 1\}$  or  $x_k = E(X \mid X \in \{x_{1:k-1}\})$

# Jensen's Inequality Example

---

Mnemonic example:

$f(x) = x^2$  : strictly convex

$\mathbf{X} = [-1; +1]$

$\mathbf{p} = [1/2; 1/2]$

$E \mathbf{X} = 0$

$f(E \mathbf{X}) = 0$

$E f(\mathbf{X}) = 1 > f(E \mathbf{X})$

# Relative Entropy

---

Relative Entropy or Kullback-Leibler Divergence  
between two probability mass vectors  $\mathbf{p}$  and  $\mathbf{q}$

$$D(\mathbf{p} \parallel \mathbf{q}) = \sum_{x \in \mathcal{X}} p(x) \log \frac{p(x)}{q(x)} = E_{\mathbf{p}} \log \frac{p(X)}{q(X)} = E_{\mathbf{p}} (-\log q(X)) - H(X)$$

where  $E_{\mathbf{p}}$  denotes an expectation performed using probabilities  $\mathbf{p}$

$D(\mathbf{p} \parallel \mathbf{q})$  measures the “distance” between the probability mass functions  $\mathbf{p}$  and  $\mathbf{q}$ .

We must have  $p_i=0$  whenever  $q_i=0$  else  $D(\mathbf{p} \parallel \mathbf{q})=\infty$

Beware:  $D(\mathbf{p} \parallel \mathbf{q})$  is not a true distance because:

- (1) it is asymmetric between  $\mathbf{p}$ ,  $\mathbf{q}$  and
- (2) it does not satisfy the triangle inequality.

# Relative Entropy Example

---

$$\mathbf{x} = [1 \ 2 \ 3 \ 4 \ 5 \ 6]^T$$

$$\mathbf{p} = \left[ \frac{1}{6} \ \frac{1}{6} \ \frac{1}{6} \ \frac{1}{6} \ \frac{1}{6} \ \frac{1}{6} \right] \Rightarrow H(\mathbf{p}) = 2.585$$

$$\mathbf{q} = \left[ \frac{1}{10} \ \frac{1}{10} \ \frac{1}{10} \ \frac{1}{10} \ \frac{1}{10} \ \frac{1}{2} \right] \Rightarrow H(\mathbf{q}) = 2.161$$

$$D(\mathbf{p} \parallel \mathbf{q}) = E_{\mathbf{p}}(-\log q_x) - H(\mathbf{p}) = 2.935 - 2.585 = 0.35$$

$$D(\mathbf{q} \parallel \mathbf{p}) = E_{\mathbf{q}}(-\log p_x) - H(\mathbf{q}) = 2.585 - 2.161 = 0.424$$

# Information Inequality

---

Information (Gibbs') Inequality:  $D(\mathbf{p} \parallel \mathbf{q}) \geq 0$

- Define  $\mathcal{A} = \{x : p(x) > 0\} \subseteq \mathcal{X}$

- Proof  $-D(\mathbf{p} \parallel \mathbf{q}) = -\sum_{x \in \mathcal{A}} p(x) \log \frac{p(x)}{q(x)} = \sum_{x \in \mathcal{A}} p(x) \log \frac{q(x)}{p(x)}$   

$$\leq \log \left( \sum_{x \in \mathcal{A}} p(x) \frac{q(x)}{p(x)} \right) = \log \left( \sum_{x \in \mathcal{A}} q(x) \right) \leq \log \left( \sum_{x \in \mathcal{X}} q(x) \right) = \log 1 = 0$$

If  $D(\mathbf{p} \parallel \mathbf{q})=0$ : Since  $\log(\cdot)$  is strictly concave we have equality in the proof only if  $q(x)/p(x)$ , the argument of  $\log$ , equals a constant.

But  $\sum_{x \in \mathcal{X}} p(x) = \sum_{x \in \mathcal{X}} q(x) = 1$  so the constant must be 1 and  $\mathbf{p} \equiv \mathbf{q}$

# Information Inequality Corollaries

---

- Uniform distribution has highest entropy
  - Set  $\mathbf{q} = [|\mathcal{X}|^{-1}, \dots, |\mathcal{X}|^{-1}]^T$  giving  $H(\mathbf{q}) = \log |\mathcal{X}|$  bits

$$D(\mathbf{p} \parallel \mathbf{q}) = E_{\mathbf{p}} \{-\log q(x)\} - H(\mathbf{p}) = \log |\mathcal{X}| - H(\mathbf{p}) \geq 0$$

- Mutual Information is non-negative

$$\begin{aligned} I(y; x) &= H(x) + H(y) - H(x, y) = E \log \frac{p(x, y)}{p(x)p(y)} \\ &= D(\mathbf{p}_{x, y} \parallel \mathbf{p}_x \otimes \mathbf{p}_y) \geq 0 \end{aligned}$$

with equality only if  $p(x, y) \equiv p(x)p(y) \Leftrightarrow x$  and  $y$  are independent.

# More Corollaries

---

- Conditioning reduces entropy

$$0 \leq I(x; y) = H(y) - H(y | x) \Rightarrow H(y | x) \leq H(y)$$

with equality only if  $x$  and  $y$  are independent.

- Independence Bound

$$H(x_{1:n}) = \sum_{i=1}^n H(x_i | x_{1:i-1}) \leq \sum_{i=1}^n H(x_i)$$

with equality only if all  $x_i$  are independent.

E.g.: If all  $x_i$  are identical  $H(x_{1:n}) = H(x_1)$

# Conditional Independence Bound

---

- Conditional Independence Bound

$$H(x_{1:n} | y_{1:n}) = \sum_{i=1}^n H(x_i | x_{1:i-1}, y_{1:n}) \leq \sum_{i=1}^n H(x_i | y_i)$$

- Mutual Information Independence Bound

If all  $x_i$  are independent or, by symmetry, if all  $y_i$  are independent:

$$\begin{aligned} I(x_{1:n}; y_{1:n}) &= H(x_{1:n}) - H(x_{1:n} | y_{1:n}) \\ &\geq \sum_{i=1}^n H(x_i) - \sum_{i=1}^n H(x_i | y_i) = \sum_{i=1}^n I(x_i; y_i) \end{aligned}$$

E.g.: If  $n=2$  with  $x_i$  i.i.d. Bernoulli ( $p=0.5$ ) and  $y_1=x_2$  and  $y_2=x_1$ , then  $I(x_i; y_i)=0$  but  $I(x_{1:2}; y_{1:2}) = 2$  bits.

# Summary

---

- Mutual Information  $I(x; y) = H(x) - H(x | y) \leq H(x)$
- Jensen's Inequality:  $f(x)$  convex  $\Rightarrow Ef(x) \geq f(Ex)$
- Relative Entropy:
  - $D(\mathbf{p} \parallel \mathbf{q}) = 0$  iff  $\mathbf{p} \equiv \mathbf{q}$   $D(\mathbf{p} \parallel \mathbf{q}) = E_{\mathbf{p}} \log \frac{p(x)}{q(x)} \geq 0$
- Corollaries
  - Uniform Bound: Uniform  $\mathbf{p}$  maximizes  $H(\mathbf{p})$
  - $I(x; y) \geq 0 \Rightarrow$  Conditioning reduces entropy
  - Indep bounds:  $H(x_{1:n}) \leq \sum_{i=1}^n H(x_i)$   $H(x_{1:n} | y_{1:n}) \leq \sum_{i=1}^n H(x_i | y_i)$
  - $I(x_{1:n}; y_{1:n}) \geq \sum_{i=1}^n I(x_i; y_i)$  if  $x_i$  or  $y_i$  are indep

# Lecture 3

---

- Symbol codes
  - uniquely decodable
  - prefix
- Kraft Inequality
- Minimum code length
- Fano Code

# Symbol Codes

---

- **Symbol Code:**  $C$  is a mapping  $\mathcal{X} \rightarrow \mathcal{D}^+$ 
  - $\mathcal{D}^+$  = set of all finite length strings from  $\mathcal{D}$
  - e.g.  $\{\text{E}, \text{F}, \text{G}\} \rightarrow \{0,1\}^+ : C(\text{E})=0, C(\text{F})=10, C(\text{G})=11$
- **Extension:**  $C^+$  is mapping  $\mathcal{X}^+ \rightarrow \mathcal{D}^+$  formed by concatenating  $C(x_i)$  without punctuation
  - e.g.  $C^+(\text{E}\text{F}\text{E}\text{E}\text{G}\text{E}) = 01000110$
- **Non-singular:**  $x_1 \neq x_2 \Rightarrow C(x_1) \neq C(x_2)$
- **Uniquely Decodable:**  $C^+$  is non-singular
  - that is  $C^+(x^+)$  is unambiguous

# Prefix Codes

---

- Instantaneous or Prefix Code:  
No codeword is a prefix of another
- Prefix  $\Rightarrow$  Uniquely Decodable  $\Rightarrow$  Non-singular

## Examples:

- $C(\text{E}, \text{F}, \text{G}, \text{H}) = (0, 1, 00, 11)$   $\overline{P}\overline{U}$
- $C(\text{E}, \text{F}) = (0, 101)$   $PU$
- $C(\text{E}, \text{F}) = (1, 101)$   $\overline{P}U$
- $C(\text{E}, \text{F}, \text{G}, \text{H}) = (00, 01, 10, 11)$   $PU$
- $C(\text{E}, \text{F}, \text{G}, \text{H}) = (0, 01, 011, 111)$   $\overline{P}U$

# Code Tree

Prefix code:  $C(\text{E}, \text{F}, \text{G}, \text{H}) = (00, 11, 100, 101)$

Form a  $D$ -ary tree where  $D = |\mathbf{D}|$

- $D$  branches at each node
- Each node along the path to a leaf is a prefix of the leaf  
 $\Rightarrow$  can't be a leaf itself
- Some leaves may be unused  
 all used  $\Rightarrow |\mathbf{X}| - 1$  is a multiple of  $D - 1$

111011000000  $\rightarrow$  FHGE

# Kraft Inequality (binary prefix)

- Label each node at depth  $l$  with  $2^{-l}$
- Each node equals the sum of all its leaves
- Codeword lengths:  
 $l_1, l_2, \dots, l_{|\mathbf{x}|} \Rightarrow \sum_{i=1}^{|\mathbf{x}|} 2^{-l_i} \leq 1$
- Equality iff all leaves are utilised
- Total code budget = 1  
 Code 00 uses up  $\frac{1}{4}$  of the budget  
 Code 100 uses up  $\frac{1}{8}$  of the budget

Same argument works with D-ary tree

# Kraft Inequality

---

If uniquely decodable  $C$  has codeword lengths

$$l_1, l_2, \dots, l_{|\mathbf{x}|}, \text{ then } \sum_{i=1}^{|\mathbf{x}|} D^{-l_i} \leq 1$$

**Proof:** Let  $S = \sum_{i=1}^{|\mathbf{x}|} D^{-l_i}$  and  $M = \max l_i$  then for any  $N$ ,

$$\begin{aligned} S^N &= \left( \sum_{i=1}^{|\mathbf{x}|} D^{-l_i} \right)^N = \sum_{i_1=1}^{|\mathbf{x}|} \sum_{i_2=1}^{|\mathbf{x}|} \dots \sum_{i_N=1}^{|\mathbf{x}|} D^{-(l_{i_1} + l_{i_2} + \dots + l_{i_N})} = \sum_{\mathbf{x} \in \mathbf{X}^N} D^{-\text{length}\{C^+(\mathbf{x})\}} \\ &= \sum_{l=1}^{NM} D^{-l} |\mathbf{x} : l = \text{length}\{C^+(\mathbf{x})\}| \leq \sum_{l=1}^{NM} D^{-l} D^l = \sum_{l=1}^{NM} 1 = NM \end{aligned}$$

If  $S > 1$  then  $S^N > NM$  for some  $N$ . Hence  $S \leq 1$

# Converse to Kraft Inequality

---

If  $\sum_{i=1}^{|X|} D^{-l_i} \leq 1$  then  $\exists$  a prefix code with codeword lengths  $l_1, l_2, \dots, l_{|X|}$

Proof:

- Assume  $l_i \leq l_{i+1}$  and think of codewords as base- $D$  decimals  $0.d_1d_2\dots d_{l_i}$
- Let codeword  $c_k = \sum_{i=1}^{k-1} D^{-l_i}$  with  $l_k$  digits
- For any  $j < k$  we have  $c_k = c_j + \sum_{i=j}^{k-1} D^{-l_i} \geq c_j + D^{-l_j}$
- So  $c_j$  cannot be a prefix of  $c_k$  because they differ in the first  $l_j$  digits.

$\Rightarrow$  non-prefix symbol codes are a waste of time

# Kraft Converse Example

Suppose  $\mathbf{l} = [2; 2; 3; 3; 3] \Rightarrow \sum_{i=1}^5 2^{-l_i} = 0.875 \leq 1$

| $l_k$ | $c_k = \sum_{i=1}^{k-1} 2^{-l_i}$ | Code |
|-------|-----------------------------------|------|
| 2     | $0.0 = 0.00_2$                    | 00   |
| 2     | $0.25 = 0.01_2$                   | 01   |
| 3     | $0.5 = 0.100_2$                   | 100  |
| 3     | $0.625 = 0.101_2$                 | 101  |
| 3     | $0.75 = 0.110_2$                  | 110  |

Each  $c_k$  is obtained by adding 1 to the LSB of the previous row

For code, express  $c_k$  in binary and take the first  $l_k$  binary places

# Minimum Code Length

---

If  $l(x) = \text{length}(C(x))$  then  $C$  is **optimal** if  $L_C = E l(X)$  is as small as possible.

Uniquely decodable code  $\Rightarrow L_C \geq H(X)/\log_2 D$

**Proof:** We define  $\mathbf{q}$  by  $q(x) = c^{-1} D^{-l(x)}$  where  $c = \sum_x D^{-l(x)} \leq 1$

$$\begin{aligned} L_C - H(X)/\log_2 D &= E l(X) + E \log_D p(X) \\ &= E \left( -\log_D D^{-l(x)} + \log_D p(x) \right) = E \left( -\log_D c q(x) + \log_D p(x) \right) \\ &= E \left( \log_D \frac{p(x)}{q(x)} \right) - \log_D c = \log_D 2(D(\mathbf{p} \parallel \mathbf{q}) - \log c) \geq 0 \end{aligned}$$

with equality only if  $c=1$  and  $D(\mathbf{p} \parallel \mathbf{q}) = 0 \Rightarrow \mathbf{p} = \mathbf{q} \Rightarrow l(x) = -\log_D(x)$

# Fano Code

## Fano Code (also called Shannon-Fano code)

1. Put probabilities in decreasing order
2. Split as close to 50-50 as possible; repeat with each half

|   |      |   |      |
|---|------|---|------|
| a | 0.20 | 0 | 00   |
| b | 0.19 | 1 | 010  |
| c | 0.17 | 1 | 011  |
| d | 0.15 | 0 | 100  |
| e | 0.14 | 1 | 101  |
| f | 0.06 | 1 | 110  |
| g | 0.05 | 1 | 1110 |
| h | 0.04 | 1 | 1111 |

$$H(\mathbf{p}) = 2.81 \text{ bits}$$

$$L_{SF} = 2.89 \text{ bits}$$

$$\text{Always } H(\mathbf{p}) \leq L_F \leq H(\mathbf{p}) + 1 - 2 \min(\mathbf{p}) \leq H(\mathbf{p}) + 1$$

Not necessarily optimal: the best code for this  $\mathbf{p}$  actually has  $L = 2.85$  bits

# Summary

---

- Kraft Inequality for D-ary codes:
  - any uniquely decodable C has  $\sum_{i=1}^{|X|} D^{-l_i} \leq 1$
  - If  $\sum_{i=1}^{|X|} D^{-l_i} \leq 1$  then you can create a prefix code
- Uniquely decodable  $\Rightarrow L_C \geq H(X) \log_2 D$
- Fano code
  - Order the probabilities, then repeatedly split in half to form a tree.
  - Intuitively natural but not optimal

# Lecture 4

---

- Optimal Symbol Code
  - Optimality implications
  - Huffman Code
- Optimal Symbol Code lengths
  - Entropy Bound
- Shannon Code

# Huffman Code

---

An Optimal Binary prefix code must satisfy:

1.  $p(x_i) > p(x_j) \Rightarrow l_i \leq l_j$  (else swap codewords)
2. The two longest codewords have the same length (else chop a bit off the longer codeword)
3.  $\exists$  two longest codewords differing only in the last bit (else chop a bit off all of them)

## Huffman Code construction

1. Take the two smallest  $p(x_i)$  and assign each a different last bit. Then merge into a single symbol.
2. Repeat step 1 until only one symbol remains

# Huffman Code Example

$$\mathcal{X} = [a, b, c, d, e], p_{\mathcal{X}} = [0.25 \ 0.25 \ 0.2 \ 0.15 \ 0.15]$$

Read diagram **backwards** for codewords:

$$C(\mathcal{X}) = [00 \ 10 \ 11 \ 010 \ 011], L_C = 2.3, H(\mathcal{X}) = 2.286$$

For D-ary code, first add extra zero-probability symbols until  $|\mathcal{X}|-1$  is a multiple of  $D-1$  and then group D symbols at a time

# Huffman Code is Optimal Prefix Code

Huffman traceback gives codes for progressively larger alphabets:

$$\mathbf{p}_2 = [0.55 \ 0.45],$$

$$\mathbf{c}_2 = [0 \ 1], L_2 = 1$$

$$\mathbf{p}_3 = [0.25 \ 0.45 \ 0.3],$$

$$\mathbf{c}_3 = [00 \ 1 \ 01], L_3 = 1.55$$

$$\mathbf{p}_4 = [0.25 \ 0.25 \ 0.2 \ 0.3],$$

$$\mathbf{c}_4 = [00 \ 10 \ 11 \ 01], L_4 = 2$$

$$\mathbf{p}_5 = [0.25 \ 0.25 \ 0.2 \ 0.15 \ 0.15],$$

$$\mathbf{c}_5 = [00 \ 10 \ 11 \ 010 \ 011], L_5 = 2.3$$

We want to show that all these codes are optimal including  $C_5$

# Huffman Optimality Proof

---

Suppose one of these codes is sub-optimal:

- $\exists m > 2$  with  $\mathbf{c}_m$  the **first** sub-optimal code (note  $\mathbf{c}_2$  is definitely optimal)
- An optimal  $\mathbf{c}'_m$  must have  $L_{\mathbf{c}'_m} < L_{\mathbf{c}_m}$
- Rearrange the symbols with longest codes in  $\mathbf{c}'_m$  so the two lowest probs  $p_i$  and  $p_j$  differ only in the last digit (doesn't change optimality)
- Merge  $x_i$  and  $x_j$  to create a new code  $\mathbf{c}'_{m-1}$  as in Huffman procedure
- $L_{\mathbf{c}'_{m-1}} = L_{\mathbf{c}_m} - p_i - p_j$  since identical except 1 bit shorter with prob  $p_i + p_j$
- But also  $L_{\mathbf{c}_{m-1}} = L_{\mathbf{c}_m} - p_i - p_j$  hence  $L_{\mathbf{c}'_{m-1}} < L_{\mathbf{c}_{m-1}}$  which contradicts assumption that  $\mathbf{c}_m$  is the **first** sub-optimal code

Note: Huffman is just one out of many possible optimal codes

# How short are Optimal Codes?

---

Huffman is optimal but hard to estimate its length.

If  $l(x) = \text{length}(C(x))$  then  $C$  is **optimal** if  $L_C = E l(x)$  is as small as possible.

We want to minimize  $\sum_{x \in \mathcal{X}} p(x)l(x)$  subject to

1.  $\sum_{x \in \mathcal{X}} D^{-l(x)} \leq 1$
2. all the  $l(x)$  are integers

Simplified version:

Ignore condition 2 and assume condition 1 is satisfied with equality.

less restrictive so lengths may be shorter than actually possible  $\Rightarrow$  lower bound

# Optimal Codes (non-integer $l_i$ )

---

- Minimize  $\sum_{i=1}^{|X|} p(x_i) l_i$  subject to  $\sum_{i=1}^{|X|} D^{-l_i} = 1$

Use lagrange multiplier:

Define  $J = \sum_{i=1}^{|X|} p(x_i) l_i + \lambda \sum_{i=1}^{|X|} D^{-l_i}$  and set  $\frac{\partial J}{\partial l_i} = 0$

$$\frac{\partial J}{\partial l_i} = p(x_i) - \lambda \ln(D) D^{-l_i} = 0 \Rightarrow D^{-l_i} = p(x_i) / \lambda \ln(D)$$

$$\text{also } \sum_{i=1}^{|X|} D^{-l_i} = 1 \Rightarrow \lambda = 1 / \ln(D) \Rightarrow l_i = -\log_D(p(x_i))$$

$$\text{with these } l_i, \quad E l(x) = E - \log_D(p(x)) = \frac{E - \log_2(p(x))}{\log_2 D} = \frac{H(x)}{\log_2 D}$$

no uniquely decodable code can do better than this (Kraft inequality)

# Shannon Code

---

Round up optimal code lengths:  $l_i = \lceil -\log_D p(x_i) \rceil$

- $l_i$  are bound to satisfy the Kraft Inequality (since the optimum lengths do)

- Hence prefix code exists:

put  $l_i$  into ascending order and set

$$c_k = \sum_{i=1}^{k-1} D^{-l_i} \quad \text{or} \quad c_k = \sum_{i=1}^{k-1} p(x_i)$$

equally good  
since  $p(x_i) \geq D^{-l_i}$

to  $l_i$  places

- Average length:  $\frac{H(X)}{\log_2 D} \leq L_C < \frac{H(X)}{\log_2 D} + 1$  (since we added  $<1$  to optimum values)

Note: since Huffman code is optimal, it also satisfies these limits

# Shannon Code Examples

---

Example 1  
(good)

$$\mathbf{p}_x = [0.5 \quad 0.25 \quad 0.125 \quad 0.125]$$

$$-\log_2 \mathbf{p}_x = [1 \quad 2 \quad 3 \quad 3]$$

$$\mathbf{l}_x = \lceil -\log_2 \mathbf{p}_x \rceil = [1 \quad 2 \quad 3 \quad 3]$$

$$L_C = 1.75 \text{ bits}, \quad H(x) = 1.75 \text{ bits}$$

Dyadic probabilities

Example 2  
(bad)

$$\mathbf{p}_x = [0.99 \quad 0.01]$$

$$-\log_2 \mathbf{p}_x = [0.0145 \quad 6.64]$$

$$\mathbf{l}_x = \lceil -\log_2 \mathbf{p}_x \rceil = [1 \quad 7] \quad (\text{obviously stupid to use } 7)$$

$$L_C = 1.06 \text{ bits}, \quad H(x) = 0.08 \text{ bits}$$

We can make  $H(x)+1$  bound tighter by encoding longer blocks as a super-symbol

# Shannon versus Huffman

## Shannon

$$\mathbf{p}_x = [0.36 \quad 0.34 \quad 0.25 \quad 0.05] \Rightarrow H(x) = 1.78 \text{ bits}$$

$$-\log_2 \mathbf{p}_x = [1.47 \quad 1.56 \quad 2 \quad 4.32]$$

$$\mathbf{l}_S = \lceil -\log_2 \mathbf{p}_x \rceil = [2 \quad 2 \quad 2 \quad 5]$$

$$L_S = 2.15 \text{ bits}$$

## Huffman

$$\mathbf{l}_H = [1 \quad 2 \quad 3 \quad 3]$$

$$L_H = 1.94 \text{ bits}$$

Individual codewords may be longer in Huffman than Shannon but not the average

# Shannon Competitive Optimality

---

- $l(x)$  is length of a uniquely decodable code
  - $l_S(x) = \lceil -\log p(x) \rceil$  is length of Shannon code
- then  $p(l(x) \leq l_S(x) - c) \leq 2^{1-c}$

**Proof:** Define  $\mathcal{A} = \{x : p(x) < 2^{-l(x)-c+1}\}$  x with especially short  $l(x)$

$$p(l(x) \leq \lceil -\log p(x) \rceil - c) \leq p(l(x) < -\log p(x) - c + 1) = p(x \in \mathcal{A})$$

$$\begin{aligned}
 &= \sum_{x \in \mathcal{A}} p(x) \leq \sum_{x \in \mathcal{A}} \max(p(x) \mid x \in \mathcal{A}) < \sum_{x \in \mathcal{A}} 2^{-l(x)-c+1} \\
 &\leq \sum_x 2^{-l(x)-c+1} = 2^{-(c-1)} \sum_x 2^{-l(x)} \leq 2^{-(c-1)} \quad \text{Kraft inequality}
 \end{aligned}$$

← now over all x

No other symbol code can do much better than Shannon code most of the time

# Dyadic Competitive optimality

If  $\mathbf{p}$  is dyadic  $\Leftrightarrow \log p(x_i)$  is integer,  $\forall i \Rightarrow$  Shannon is optimal

then  $p(l(x) < l_s(x)) \leq p(l(x) > l_s(x))$  with equality iff  $l(x) \equiv l_s(x)$

## Proof:

– Define  $\text{sgn}(x) = \{-1, 0, +1\}$  for  $\{x < 0, x = 0, x > 0\}$

– Note:  $\text{sgn}(i) \leq 2^i - 1$  for all integers  $i$  equality iff  $i = 0$  or  $1$

$$p(l_s(x) > l(x)) - p(l_s(x) < l(x)) = \sum_x p(x) \text{sgn}(l_s(x) - l(x))$$

$$\stackrel{\text{A}}{\leq} \sum_x p(x) (2^{l_s(x) - l(x)} - 1) = -1 + \sum_x 2^{-l_s(x)} 2^{l_s(x) - l(x)} \quad \text{sgn() property dyadic} \Rightarrow p = 2^{-l}$$

$$= -1 + \sum_x 2^{-l(x)} \stackrel{\text{B}}{\leq} -1 + 1 = 0 \quad \text{Kraft inequality}$$

Rival code cannot be shorter than Shannon more than half the time.

equality @ A  $\Rightarrow l(x) = l_s(x) - \{0, 1\}$  but  $l(x) < l_s(x)$  would violate Kraft @ B since Shannon has  $\Sigma = 1$

# Shannon with wrong distribution

---

If the real distribution of  $x$  is  $\mathbf{p}$  but you assign Shannon lengths using the distribution  $\mathbf{q}$  what is the penalty ?

Answer:  $D(\mathbf{p} \parallel \mathbf{q})$

**Proof:**

$$\begin{aligned} E l(X) &= \sum_i p_i \lceil -\log q_i \rceil < \sum_i p_i (1 - \log q_i) \\ &= \sum_i p_i \left( 1 + \log \frac{p_i}{q_i} - \log p_i \right) \\ &= 1 + D(\mathbf{p} \parallel \mathbf{q}) + H(\mathbf{p}) \end{aligned}$$

Therefore

$$H(\mathbf{p}) + D(\mathbf{p} \parallel \mathbf{q}) \leq E l(x) < H(\mathbf{p}) + D(\mathbf{p} \parallel \mathbf{q}) + 1$$

Proof of lower limit  
is similar but  
without the 1

If you use the wrong distribution, the penalty is  $D(\mathbf{p} \parallel \mathbf{q})$

# Summary

---

- Any uniquely decodable code:  $E l(x) \geq H_D(x) = \frac{H(x)}{\log_2 D}$
- **Fano Code:**  $H_D(x) \leq E l(x) \leq H_D(x) + 1$ 
  - Intuitively natural top-down design
- **Huffman Code:**
  - Bottom-up design
  - Optimal  $\Rightarrow$  at least as good as Shannon/Fano
- **Shannon Code:**  $l_i = \lceil -\log_D p_i \rceil$   $H_D(x) \leq E l(x) \leq H_D(x) + 1$ 
  - Close to optimal and easier to prove bounds

Note: Not everyone agrees on the names of Shannon and Fano codes

# Lecture 5

---

- Stochastic Processes
- Entropy Rate
- Markov Processes
- Hidden Markov Processes

# Stochastic process

---

Stochastic Process  $\{x_i\} = x_1, x_2, \dots$

Entropy:  $H(\{x_i\}) = H(x_1) + H(x_2 | x_1) + \dots \stackrel{\text{often}}{=} \infty$

Entropy Rate:  $H(\mathbf{X}) = \lim_{n \rightarrow \infty} \frac{1}{n} H(x_{1:n})$  if limit exists

- Entropy rate estimates the additional entropy per new sample.
- Gives a lower bound on number of code bits per sample.
- If the  $x_i$  are not i.i.d. the entropy rate limit may not exist.

Examples:

- $x_i$  i.i.d. random variables:  $H(\mathbf{X}) = H(x_i)$
- $x_i$  indep,  $H(x_i) = 0$  1 00 11 0000 1111 00000000 ... no convergence

# Lemma: Limit of Cesàro Mean

---

$$a_n \rightarrow b \quad \Rightarrow \quad \frac{1}{n} \sum_{k=1}^n a_k \rightarrow b$$

## Proof:

- Choose  $\varepsilon > 0$  and find  $N_0$  such that  $|a_n - b| < \frac{1}{2}\varepsilon \quad \forall n > N_0$
- Set  $N_1 = 2N_0\varepsilon^{-1} \max(|a_r - b|) \quad \text{for } r \in [1, N_0]$
- Then  $\forall n > N_1$ 

$$\begin{aligned} n^{-1} \sum_{k=1}^n |a_k - b| &= n^{-1} \sum_{k=1}^{N_0} |a_k - b| + n^{-1} \sum_{k=N_0+1}^n |a_k - b| \\ &\leq N_1^{-1} N_0 \left( \frac{1}{2} N_0^{-1} N_1 \varepsilon \right) + n^{-1} n \left( \frac{1}{2} \varepsilon \right) \\ &= \frac{1}{2} \varepsilon + \frac{1}{2} \varepsilon = \varepsilon \end{aligned}$$

The partial means of  $a_k$  are called Cesàro Means

# Stationary Process

---

Stochastic Process  $\{x_i\}$  is **stationary** iff

$$p(x_{1:n} = a_{1:n}) = p(x_{k+(1:n)} = a_{1:n}) \quad \forall k, n, a_i \in \mathcal{X}$$

If  $\{x_i\}$  is stationary then  $H(\mathcal{X})$  exists and

$$H(\mathcal{X}) = \lim_{n \rightarrow \infty} \frac{1}{n} H(x_{1:n}) = \lim_{n \rightarrow \infty} H(x_n \mid x_{1:n-1})$$

**Proof:** 
$$0 \leq H(x_n \mid x_{1:n-1}) \stackrel{(a)}{\leq} H(x_n \mid x_{2:n-1}) \stackrel{(b)}{=} H(x_{n-1} \mid x_{1:n-2})$$

(a) conditioning reduces entropy, (b) stationarity

Hence  $H(x_n \mid x_{1:n-1})$  is +ve, decreasing  $\Rightarrow$  tends to a limit, say  $b$

Hence from Cesàro Mean lemma:

$$H(x_k \mid x_{1:k-1}) \rightarrow b \quad \Rightarrow \quad \frac{1}{n} H(x_{1:n}) = \frac{1}{n} \sum_{k=1}^n H(x_k \mid x_{1:k-1}) \rightarrow b = H(\mathcal{X})$$

# Block Coding

---

If  $x_i$  is a **stochastic process**

- encode blocks of  $n$  symbols
- 1-bit penalty of Shannon/Huffman is now shared between  $n$  symbols

$$n^{-1}H(X_{1:n}) \leq n^{-1}E l(X_{1:n}) \leq n^{-1}H(X_{1:n}) + n^{-1}$$

If **entropy rate** of  $x_i$  exists ( $\Leftarrow x_i$  is **stationary**)

$$n^{-1}H(X_{1:n}) \rightarrow H(\mathbf{X}) \quad \Rightarrow \quad n^{-1}E l(X_{1:n}) \rightarrow H(\mathbf{X})$$

The extra 1 bit inefficiency becomes insignificant for large blocks

# Block Coding Example

$$\mathbf{X} = [A; B], \mathbf{p}_X = [0.9; 0.1]$$

$$H(x_i) = 0.469$$

- $n=1$ 

|      |     |     |  |
|------|-----|-----|--|
| sym  | A   | B   |  |
| prob | 0.9 | 0.1 |  |
| code | 0   | 1   |  |

 $n^{-1} E l = 1$
- $n=2$ 

|      |      |      |      |      |  |
|------|------|------|------|------|--|
| sym  | AA   | AB   | BA   | BB   |  |
| prob | 0.81 | 0.09 | 0.09 | 0.01 |  |
| code | 0    | 11   | 100  | 101  |  |

 $n^{-1} E l = 0.645$
- $n=3$ 

|      |       |       |     |       |       |  |
|------|-------|-------|-----|-------|-------|--|
| sym  | AAA   | AAB   | ... | BBA   | BBB   |  |
| prob | 0.729 | 0.081 | ... | 0.009 | 0.001 |  |
| code | 0     | 101   | ... | 10010 | 10011 |  |

 $n^{-1} E l = 0.583$

# Markov Process

Discrete-valued Stochastic Process  $\{x_i\}$  is

- Independent iff  $p(x_n|x_{0:n-1})=p(x_n)$
- Markov iff  $p(x_n|x_{0:n-1})=p(x_n|x_{n-1})$ 
  - time-invariant iff  $p(x_n=b|x_{n-1}=a) = p_{ab}$  indep of  $n$
  - Transition matrix:  $\mathbf{T} = \{t_{ab}\}$ 
    - Rows sum to 1:  $\mathbf{T}\mathbf{1} = \mathbf{1}$  where  $\mathbf{1}$  is a vector of 1's
    - $\mathbf{p}_n = \mathbf{T}^T \mathbf{p}_{n-1}$
    - Stationary distribution:  $\mathbf{p}_\$ = \mathbf{T}^T \mathbf{p}_\$$

Independent Stochastic Process is easiest to deal with, Markov is next easiest

# Stationary Markov Process

---

If a Markov process is

- a) **irreducible**: you can go from any  $a$  to any  $b$  in a finite number of steps
  - irreducible iff  $(\mathbf{I} + \mathbf{T}^T)^{|\mathcal{X}|-1}$  has no zero entries
- b) **aperiodic**:  $\forall a$ , the possible times to go from  $a$  to  $a$  have highest common factor = 1

then it has exactly one stationary distribution,  $\mathbf{p}_\$$ .

- $\mathbf{p}_\$$  is the eigenvector of  $\mathbf{T}^T$  with  $\lambda = 1$ :  $\mathbf{T}^T \mathbf{p}_\$ = \mathbf{p}_\$$
- $\mathbf{T}^n \xrightarrow{n \rightarrow \infty} \mathbf{1} \mathbf{p}_\$^T$  where  $\mathbf{1} = [1 \ 1 \ \dots \ 1]^T$

# Chess Board

$$H(\mathbf{p}_1)=0, \quad H(\mathbf{p}_1 | \mathbf{p}_0)=0$$

## Random Walk

- Move  $\leftrightarrow \updownarrow \nearrow \nwarrow \searrow \swarrow$  equal prob

- $\mathbf{p}_1 = [1 \ 0 \ \dots \ 0]^T$

- $H(\mathbf{p}_1) = 0$

- $\mathbf{p}_\$ = 1/40 \times [3 \ 5 \ 3 \ 5 \ 8 \ 5 \ 3 \ 5 \ 3]^T$

- $H(\mathbf{p}_\$) = 3.0855$

- $H(\mathbf{X}) = \lim_{n \rightarrow \infty} H(\mathbf{x}_n | \mathbf{x}_{n-1}) = \sum_{i,j} -p_{\$,i} t_{i,j} \log(t_{i,j})$

- $H(\mathbf{X}) = 2.2365$

Time-invariant and  $\mathbf{p}_1 = \mathbf{p}_\$ \Rightarrow$  stationary

# Chess Board Frames

$$H(p_1)=0, \quad H(p_1 | p_0)=0$$

$$H(p_2)=1.58496, \quad H(p_2 | p_1)=1.58496$$

$$H(p_3)=3.10287, \quad H(p_3 | p_2)=2.54795$$

$$H(p_4)=2.99553, \quad H(p_4 | p_3)=2.09299$$

$$H(p_5)=3.111, \quad H(p_5 | p_4)=2.30177$$

$$H(p_6)=3.07129, \quad H(p_6 | p_5)=2.20683$$

$$H(p_7)=3.09141, \quad H(p_7 | p_6)=2.24987$$

$$H(p_8)=3.0827, \quad H(p_8 | p_7)=2.23038$$

# ALOHA Wireless Example

---

$M$  users share wireless transmission channel

- For each user independently in each timeslot:
  - if its queue is non-empty it transmits with prob  $q$
  - a new packet arrives for transmission with prob  $p$
- If two packets collide, they stay in the queues
- At time  $t$ , queue sizes are  $\mathbf{x}_t = (n_1, \dots, n_M)$ 
  - $\{\mathbf{x}_t\}$  is Markov since  $p(\mathbf{x}_t)$  depends only on  $\mathbf{x}_{t-1}$

Transmit vector is  $\mathbf{y}_t$  :

$$p(y_{i,t} = 1) = \begin{cases} 0 & x_{i,t} = 0 \\ q & x_{i,t} > 0 \end{cases}$$

- $\{\mathbf{y}_t\}$  is not Markov since  $p(\mathbf{y}_t)$  is determined by  $\mathbf{x}_t$  but is not determined by  $\mathbf{y}_{t-1}$ .  $\{\mathbf{y}_t\}$  is called a **Hidden Markov Process**.

# ALOHA example

Waiting Packets | TX en

|                      |   |   |   |   |   |   |   |   |
|----------------------|---|---|---|---|---|---|---|---|
| <b>x:</b>            | 3 | 2 | 1 | 2 | 1 | 0 | 1 | 2 |
|                      | 0 | 1 | 1 | 1 | 1 | 2 | 2 | 1 |
| TX enable, <b>e:</b> | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 1 |
|                      | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |
| <b>y:</b>            | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 1 |
|                      | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |

$\mathbf{y} = (\mathbf{x} > 0)\mathbf{e}$  is a deterministic function of the Markov  $[\mathbf{x}; \mathbf{e}]$

# Hidden Markov Process

---

If  $\{x_i\}$  is a stationary Markov process and  $y=f(x)$  then  $\{y_i\}$  is a stationary Hidden Markov process.

What is entropy rate  $H(\mathcal{Y})$  ?

- Stationarity  $\Rightarrow H(y_n | y_{1:n-1}) \geq H(\mathcal{Y})$  and  $\xrightarrow{n \rightarrow \infty} H(\mathcal{Y})$
- Also  $H(y_n | y_{1:n-1}, x_1) \stackrel{(1)}{\leq} H(\mathcal{Y})$  and  $\stackrel{(2)}{\xrightarrow{n \rightarrow \infty}} H(\mathcal{Y})$

So  $H(\mathcal{Y})$  is sandwiched between two quantities which converge to the same value for large  $n$ .

Proof of (1) and (2) on next slides

# Hidden Markov Process – (1)

---

Proof (1):  $H(\mathcal{Y}_n | \mathcal{Y}_{1:n-1}, \mathcal{X}_1) \leq H(\mathcal{Y})$

$$H(\mathcal{Y}_n | \mathcal{Y}_{1:n-1}, \mathcal{X}_1) = H(\mathcal{Y}_n | \mathcal{Y}_{1:n-1}, \mathcal{X}_{-k:1}) \quad \forall k \quad \text{\textcolor{teal}{x markov}}$$

$$= H(\mathcal{Y}_n | \mathcal{Y}_{1:n-1}, \mathcal{X}_{-k:1}, \mathcal{Y}_{-k:1}) = H(\mathcal{Y}_n | \mathcal{Y}_{-k:n-1}, \mathcal{X}_{-k:1}) \quad \text{\textcolor{teal}{y=f(x)}}$$

$$\leq H(\mathcal{Y}_n | \mathcal{Y}_{-k:n-1}) \quad \forall k \quad \text{\textcolor{teal}{conditioning reduces entropy}}$$

$$= H(\mathcal{Y}_{k+n} | \mathcal{Y}_{0:k+n-1}) \xrightarrow{k \rightarrow \infty} H(\mathcal{Y}) \quad \text{\textcolor{teal}{y stationary}}$$

Just knowing  $\mathcal{X}_1$  in addition to  $\mathcal{Y}_{1:n-1}$  reduces the conditional entropy to below the entropy rate.

# Hidden Markov Process – (2)

---

Proof (2):  $H(y_n | y_{1:n-1}, x_1) \xrightarrow{n \rightarrow \infty} H(\mathcal{Y})$

Note that  $\sum_{n=1}^k I(x_1; y_n | y_{1:n-1}) = I(x_1; y_{1:k})$  chain rule

$$\leq H(x_1)$$
def<sup>n</sup> of  $I(A;B)$

Hence  $I(x_1; y_n | y_{1:n-1}) \xrightarrow{n \rightarrow \infty} 0$  bounded sum of non-negative terms

So  $H(y_n | y_{1:n-1}, x_1) = H(y_n | y_{1:n-1}) - I(x_1; y_n | y_{1:n-1})$  def<sup>n</sup> of  $I(A;B)$

$$\xrightarrow{n \rightarrow \infty} H(\mathcal{Y}) - 0$$

The influence of  $x_1$  on  $y_n$  decreases over time.

# Summary

---

- Entropy Rate:  $H(\mathbf{X}) = \lim_{n \rightarrow \infty} \frac{1}{n} H(X_{1:n})$  if it exists

- $\{X_i\}$  stationary:  $H(\mathbf{X}) = \lim_{n \rightarrow \infty} H(X_n | X_{1:n-1})$

- $\{X_i\}$  stationary Markov:

$$H(\mathbf{X}) = H(X_n | X_{n-1}) = \sum_{i,j} -p_{\$,i} t_{i,j} \log(t_{i,j})$$

- $\mathcal{Y} = f(\mathcal{X})$ : Hidden Markov:

$$H(\mathcal{Y}_n | \mathcal{Y}_{1:n-1}, X_1) \leq H(\mathbf{Y}) \leq H(\mathcal{Y}_n | \mathcal{Y}_{1:n-1})$$

with both sides tending to  $H(\mathbf{Y})$

# Lecture 6

---

- Stream Codes
- Arithmetic Coding
- Lempel-Ziv Coding

# Huffman: Good and Bad

---

## Good

- Shortest possible symbol code  $\frac{H(x)}{\log_2 D} \leq L_s \leq \frac{H(x)}{\log_2 D} + 1$

## Bad

- Redundancy of up to 1 bit per symbol
  - Expensive if  $H(x)$  is small
  - Less so if you use a block of  $N$  symbols
  - Redundancy equals zero iff  $p(x_i)=2^{-k(i)} \quad \forall i$
- Must recompute entire code if any symbol probability changes
  - A block of  $N$  symbols needs  $|X|^N$  pre-calculated probabilities

# Arithmetic Coding

- Take all possible blocks of  $N$  symbols and sort into lexical order,  $\mathbf{x}_r$  for  $r=1: |\mathcal{X}|^N$
- Calculate cumulative probabilities in binary:

$$Q_r = \sum_{i \leq r} p(\mathbf{x}_i), Q_0 = 0$$

- To encode  $\mathbf{x}_r$ , transmit enough binary places to define the interval  $(Q_{r-1}, Q_r)$  unambiguously.
- Use first  $l_r$  places of  $m_r 2^{-l_r}$  where  $l_r$  is least integer with

$$Q_{r-1} \leq m_r 2^{-l_r} < (m_r + 1) 2^{-l_r} \leq Q_r$$

$\mathcal{X}=[a \ b], \mathbf{p}=[0.6 \ 0.4], N=3$

Code

|                           |     |                                                                                       |          |
|---------------------------|-----|---------------------------------------------------------------------------------------|----------|
| $Q_8 = 1.0000 = 1.000000$ | bbb |    | m8=1111  |
| $Q_7 = 0.9360 = 0.111011$ | bba |    | m7=11011 |
| $Q_6 = 0.8400 = 0.110101$ | bab |    | m6=1100  |
| $Q_5 = 0.7440 = 0.101111$ | baa |    | m5=1010  |
| $Q_4 = 0.6000 = 0.100110$ | abb |    | m4=10001 |
| $Q_3 = 0.5040 = 0.100000$ | aba |    | m3=011   |
| $Q_2 = 0.3600 = 0.010111$ | aab |  | m2=0100  |
| $Q_1 = 0.2160 = 0.001101$ | aaa |  | m1=000   |
| $Q_0 = 0.0000 = 0.000000$ |     |                                                                                       |          |

# Arithmetic Coding – Code lengths

- The interval corresponding to  $x_r$  has width  $p(x_r) = Q_r - Q_{r-1} \stackrel{\Delta}{=} 2^{-d_r}$
- Define  $k_r = \lceil d_r \rceil \Rightarrow d_r \leq k_r < d_r + 1 \Rightarrow \frac{1}{2}p(x_r) < 2^{-k_r} \leq p(x_r)$
- Set  $m_r = \lceil 2^{k_r} Q_{r-1} \rceil \Rightarrow Q_{r-1} \leq m_r 2^{-k_r}$   $Q_{r-1}$  rounded up to  $k_r$  bits
- If  $(m_r + 1)2^{-k_r} \leq Q_r$  then set  $l_r = k_r$ ; otherwise
  - set  $l_r = k_r + 1$  and redefine  $m_r = \lceil 2^{l_r} Q_{r-1} \rceil \Rightarrow (m_r - 1)2^{-l_r} < Q_{r-1} \leq m_r 2^{-l_r}$
  - now  $(m_r + 1)2^{-l_r} = (m_r - 1)2^{-l_r} + 2^{-k_r} < Q_{r-1} + p(x_r) = Q_r$
- We always have  $l_r \leq k_r + 1 < d_r + 2 = -\log(p_r) + 2$ 
  - Always within 2 bits of the optimum code for the block ( $k_r$  is Shannon len)

$$d_{6,7} = -\log p(x_{6,7}) = -\log 0.096 = 3.38 \text{ bits}$$

$$Q_7 = 0.9360 = 0.111011$$

$$Q_6 = 0.8400 = 0.110101$$

$$Q_5 = 0.7440 = 0.101111$$

$$k_7 = 4, m_7 = 14, 15 \times 2^{-4} > Q_7 \quad \times$$

$$\Rightarrow l_7 = 5, m_7 = 27, 28 \times 2^{-5} \leq Q_7 \quad \checkmark$$

$$k_6 = 4, m_6 = 12, 13 \times 2^{-4} < Q_6 \quad \checkmark$$

# Arithmetic Coding - Advantages

---

- Long blocks can be used
  - Symbol blocks are sorted lexically rather than in probability order
  - Receiver can start decoding symbols before the entire code has been received
  - Transmitter and receiver can work out the codes on the fly
    - no need to store entire codebook
- Transmitter and receiver can use identical finite-precision arithmetic
  - rounding errors are the same at transmitter and receiver
  - rounding errors affect code lengths slightly but not transmission accuracy

# Arithmetic Coding Receiver

Each additional bit received narrows down the possible interval.

$\mathbf{X}=[a \ b], \mathbf{p}=[0.6 \ 0.4]$

| ...   | ...         | ...      |      | ...      | ...      | ...      | ...    |

- Min/Max give the limits of the input or output interval; identical in transmitter and receiver.
- Blue denotes transmitted bits - they are compared with the corresponding bits of the receiver's test value and Red bit show the first difference. Gray identifies unchanged words.

# Arithmetic Coding Algorithm

---

Input Symbols:  $\mathbf{X} = [a \ b]$ ,  $\mathbf{p} = [p \ q]$

$[min, max]$  = Input Probability Range

Note: only keep untransmitted bits of  $min$  and  $max$

## Coding Algorithm:

Initialize  $[min, max] = [000...0, 111...1]$

For each input symbol,  $s$

    If  $s=a$  then  $max=min+p(max-min)$  else  $min=min+p(max-min)$

    while  $min$  and  $max$  have the same MSB

        transmit MSB and set  $min=(min \ll 1)$  and  $max=(max \ll 1)+1$

    end while

end for

- Decoder is almost identical. Identical rounding errors  $\Rightarrow$  no symbol errors.
- Simple to modify algorithm for  $|X| > 2$  and/or  $D > 2$ .
- Need to protect against range underflow when  $[x \ y] = [011111..., 100000...]$ .

# Adaptive Probabilities

---

Number of guesses for next letter (a-z, space):

o r a n g e s   a n d   l e m o n s  
 17 7 8 4 1 1 2 1 1 5 1 1 1 1 1 1 1

We can change the input symbol probabilities based on the context (= the past input sequence)

**Example:** Bernoulli source with unknown  $p$ . Adapt  $p$  based on symbol frequencies so far:

$$\mathbf{X} = [a \ b], \quad \mathbf{p}_n = [1-p_n \ p_n], \quad p_n = \frac{1 + \text{count}_{1 \leq i \leq n}(x_i = b)}{1 + n}$$

# Adaptive Arithmetic Coding

$$p_n = \frac{1 + \text{count}(x_i = b)_{1 \leq i < n}}{1 + n}$$

$$p_1 = 0.5$$

$$p_2 = 1/3 \text{ or } 2/3$$

$$p_3 = 1/4 \text{ or } 1/2 \text{ or } 3/4$$

$$p_4 = \dots$$

|   |      | aaaa |  | aaaa | 0.2000 = 0.001100 |
|   | aaaa | aaaa |  | aaaa | 0.0000 = 0.000000 |
|   |      | aaaa |  | aaaa | 0.0000 = 0.000000 |

Coder and decoder only need to calculate the probabilities along the path that actually occurs

# Lempel-Ziv Coding

---

Memorize previously occurring substrings in the input data

- parse input into the shortest possible distinct ‘phrases’
- number the phrases starting from 1 (0 is the empty string)

1011010100010...

12 3 4 5 6 7

- each phrase consists of a previously occurring phrase (head) followed by an additional 0 or 1 (tail)
- transmit code for head followed by the additional bit for tail

01001121402010...

- for head use enough bits for the max phrase number so far:

100011101100001000010...

- decoder constructs an identical dictionary

prefix codes are underlined

# Lempel-Ziv Example

---

Input = 1011010100010010001001010010

## Improvement

| Dictionary |        | Send  | Decode |
|------------|--------|-------|--------|
| 0000       | $\phi$ | 1     | 1      |
| 0001       | 1      | 00    | 0      |
| 0010       | 0      | 011   | 11     |
| 0011       | 11     | 101   | 01     |
| 0100       | 01     | 1000  | 010    |
| 0101       | 010    | 0100  | 00     |
| 0110       | 00     | 0010  | 10     |
| 0111       | 10     | 1010  | 0100   |
| 1000       | 0100   | 10001 | 01001  |
| 1001       | 01001  | 10010 | 010010 |

- Each head can only be used twice so at its second use we can:
  - Omit the tail bit
  - Delete head from the dictionary and re-use dictionary entry

# LempelZiv Comments

---

Dictionary  $D$  contains  $K$  entries  $D(0), \dots, D(K-1)$ . We need to send  $M=\text{ceil}(\log K)$  bits to specify a dictionary entry. Initially  $K=1$ ,  $D(0)=\phi$  = null string and  $M=\text{ceil}(\log K) = 0$  bits.

| Input | Action                                                                                                                                                               |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | "1" $\notin D$ so send "1" and set $D(1)$ ="1". Now $K=2 \Rightarrow M=1$ .                                                                                          |
| 0     | "0" $\notin D$ so split it up as " $\phi$ "+"0" and send "0" (since $D(0)=\phi$ ) followed by "0". Then set $D(2)$ ="0" making $K=3 \Rightarrow M=2$ .               |
| 1     | "1" $\in D$ so don't send anything yet – just read the next input bit.                                                                                               |
| 1     | "11" $\notin D$ so split it up as "1" + "1" and send "01" (since $D(1)$ = "1" and $M=2$ ) followed by "1". Then set $D(3)$ ="11" making $K=4 \Rightarrow M=2$ .      |
| 0     | "0" $\in D$ so don't send anything yet – just read the next input bit.                                                                                               |
| 1     | "01" $\notin D$ so split it up as "0" + "1" and send "10" (since $D(2)$ = "0" and $M=2$ ) followed by "1". Then set $D(4)$ ="01" making $K=5 \Rightarrow M=3$ .      |
| 0     | "0" $\in D$ so don't send anything yet – just read the next input bit.                                                                                               |
| 1     | "01" $\in D$ so don't send anything yet – just read the next input bit.                                                                                              |
| 0     | "010" $\notin D$ so split it up as "01" + "0" and send "100" (since $D(4)$ = "01" and $M=3$ ) followed by "0". Then set $D(5)$ ="010" making $K=6 \Rightarrow M=3$ . |

So far we have sent 1000111011000 where dictionary entry numbers are in red.

# Lempel-Ziv properties

---

- Widely used
  - many versions: compress, gzip, TIFF, LZW, LZ77, ...
  - different dictionary handling, etc
- Excellent compression in practice
  - many files contain repetitive sequences
  - worse than arithmetic coding for text files
- Asymptotically optimum on stationary ergodic source (i.e. achieves entropy rate)
  - $\{X_i\}$  stationary ergodic  $\Rightarrow \limsup_{n \rightarrow \infty} n^{-1} l(X_{1:n}) \leq H(\mathbf{X})$  with prob 1
    - Proof: C&T chapter 12.10
  - may only approach this for an enormous file

# Summary

---

- Stream Codes
  - Encoder and decoder operate sequentially
    - no blocking of input symbols required
  - Not forced to send  $\geq 1$  bit per input symbol
    - can achieve entropy rate even when  $H(\mathbf{X}) < 1$
- Require a Perfect Channel
  - A single transmission error causes multiple wrong output symbols
  - Use finite length blocks to limit the damage

# Lecture 7

---

- Markov Chains
- Data Processing Theorem
  - you can't create information from nothing
- Fano's Inequality
  - lower bound for error in estimating  $X$  from  $Y$

# Markov Chains

---

If we have three random variables:  $x, y, z$

$$p(x, y, z) = p(z | x, y)p(y | x)p(x)$$

they form a **Markov chain**  $x \rightarrow y \rightarrow z$  if

$$p(z | x, y) = p(z | y) \Leftrightarrow p(x, y, z) = p(z | y)p(y | x)p(x)$$

A Markov chain  $x \rightarrow y \rightarrow z$  means that

- the only way that  $x$  affects  $z$  is through the value of  $y$
- if you already know  $y$ , then observing  $x$  gives you no additional information about  $z$ , i.e.  $I(x; z | y) = 0 \Leftrightarrow H(z | y) = H(z | x, y)$
- if you know  $y$ , then observing  $z$  gives you no additional information about  $x$ .

A common special case of a Markov chain is when  $z = f(y)$

# Markov Chain Symmetry

---

Iff  $x \rightarrow y \rightarrow z$

$$p(x, z | y) = \frac{p(x, y, z)}{p(y)} \stackrel{(a)}{=} \frac{p(x, y)p(z | y)}{p(y)} = p(x | y)p(z | y)$$

$$(a) \quad p(z | x, y) = p(z | y)$$

Hence  $x$  and  $z$  are conditionally independent given  $y$

Also  $x \rightarrow y \rightarrow z$  iff  $z \rightarrow y \rightarrow x$  since

$$p(x | y) = p(x | y) \frac{p(z | y)p(y)}{p(y, z)} \stackrel{(a)}{=} \frac{p(x, z | y)p(y)}{p(y, z)} = \frac{p(x, y, z)}{p(y, z)}$$

$$= p(x | y, z)$$

$$(a) \quad p(x, z | y) = p(x | y)p(z | y)$$

Markov chain property is symmetrical

# Data Processing Theorem

---

If  $x \rightarrow y \rightarrow z$  then  $I(x; y) \geq I(x; z)$

- processing  $y$  cannot add new information about  $x$

If  $x \rightarrow y \rightarrow z$  then  $I(x; y) \geq I(x; y | z)$

- Knowing  $z$  can only decrease the amount  $x$  tells you about  $y$

Proof:

$$I(x; y, z) = I(x; y) + I(x; z | y) = I(x; z) + I(x; y | z)$$

$$\text{but } I(x; z | y) \stackrel{(a)}{=} 0$$

$$\text{hence } I(x; y) = I(x; z) + I(x; y | z)$$

$$\text{so } I(x; y) \geq I(x; z) \text{ and } I(x; y) \geq I(x; y | z)$$

(a)  $I(x; z) = 0$  iff  $x$  and  $z$  are independent; Markov  $\Rightarrow p(x, z | y) = p(x | y)p(z | y)$

# Non-Markov: Conditioning can increase $I$

Noisy Channel:  $z = x + y$

- $\mathbf{X} = \mathbf{Y} = [0, 1]^T$     $\mathbf{p}_X = \mathbf{p}_Y = [1/2, 1/2]^T$
- $I(x; y) = 0$  since independent
- but  $I(x; y | z) = 1/2$

|      |    | $Z$   |       |       |
|------|----|-------|-------|-------|
|      |    | 0     | 1     | 2     |
| $XY$ | 00 | $1/4$ |       |       |
|      | 01 |       | $1/4$ |       |
|      | 10 |       | $1/4$ |       |
|      | 11 |       |       | $1/4$ |

$$\begin{aligned}
 H(x|z) &= H(y|z) = H(x, y|z) \\
 &= 0 \times 1/4 + 1 \times 1/2 + 0 \times 1/4 = 1/2 \\
 &\text{since in each case } z \neq 1 \Rightarrow H() = 0 \\
 I(x, y|z) &= H(x|z) + H(y|z) - H(x, y|z) \\
 &= 1/2 + 1/2 - 1/2 = 1/2
 \end{aligned}$$

If you know  $z$ , then  $x$  and  $y$  are no longer independent

# Long Markov Chains

---

If  $x_1 \rightarrow x_2 \rightarrow x_3 \rightarrow x_4 \rightarrow x_5 \rightarrow x_6$

then Mutual Information increases as you get closer together:

– e.g.  $I(x_3, x_4) \geq I(x_2, x_4) \geq I(x_1, x_5) \geq I(x_1, x_6)$

# Sufficient Statistics

---

If pdf of  $x$  depends on a parameter  $\theta$  and you extract a statistic  $T(x)$  from your observation,

$$\text{then } \theta \rightarrow x \rightarrow T(x) \Rightarrow I(\theta; T(x)) \leq I(\theta; x)$$

$T(x)$  is sufficient for  $\theta$  if the stronger condition:

$$\theta \rightarrow x \rightarrow T(x) \rightarrow \theta \Leftrightarrow I(\theta; T(x)) = I(\theta; x)$$

$$\Leftrightarrow \theta \rightarrow T(x) \rightarrow x \rightarrow \theta$$

$$\Leftrightarrow p(x | T(x), \theta) = p(x | T(x))$$

Example:  $x_i \sim \text{Bernoulli}(\theta)$ ,

$$T(x_{1:n}) = \sum_{i=1}^n x_i \quad p(X_{1:n} = x_{1:n} | \theta, \sum x_i = k) = \begin{cases} \binom{n}{k} \theta^k (1-\theta)^{n-k} & \text{if } \sum x_i = k \\ 0 & \text{if } \sum x_i \neq k \end{cases}$$

independent of  $\theta \Rightarrow$  sufficient

# Fano's Inequality

If we estimate  $x$  from  $y$ , what is  $p_e = p(\hat{x} \neq x)$  ?

$$H(x | y) \leq H(p_e) + p_e \log(|\mathcal{X}| - 1)$$

$$\Rightarrow p_e \geq \frac{(H(x | y) - H(p_e))^{(a)} (H(x | y) - 1)}{\log(|\mathcal{X}| - 1)} \geq \frac{(H(x | y) - 1)}{\log(|\mathcal{X}| - 1)}$$

(a) the second form is weaker but easier to use

Proof: Define a random variable  $e = (\hat{x} \neq x)?1:0$

$$H(e, x | y) = H(x | y) + H(e | x, y) = H(e | y) + H(x | e, y) \quad \text{chain rule}$$

$$\Rightarrow H(x | y) + 0 \leq H(e) + H(x | e, y) \quad H \geq 0; H(e | y) \leq H(e)$$

$$= H(e) + H(x | y, e = 0)(1 - p_e) + H(x | y, e = 1)p_e$$

$$\leq H(p_e) + 0 \times (1 - p_e) + \log(|\mathcal{X}| - 1)p_e \quad H(e) = H(p_e)$$

Fano's inequality is used whenever you need to show that errors are inevitable

# Fano Example

---

$$\mathbf{X} = \{1:5\}, \mathbf{p}_X = [0.35, 0.35, 0.1, 0.1, 0.1]^T$$

$\mathbf{Y} = \{1:2\}$  if  $x \leq 2$  then  $y=x$  with probability  $6/7$   
while if  $x > 2$  then  $y=1$  or  $2$  with equal prob.

Our best strategy is to guess  $\hat{x} = y$

$$- \mathbf{p}_{X|Y=1} = [0.6, 0.1, 0.1, 0.1, 0.1]^T$$

- actual error prob:  $p_e = 0.4$

Fano bound: 
$$p_e \geq \frac{H(X|Y) - 1}{\log(|\mathbf{X}| - 1)} = \frac{1.771 - 1}{\log(4)} = 0.3855$$

Main use: to show when error free transmission is impossible since  $p_e > 0$

# Summary

---

- **Markov:**  $x \rightarrow y \rightarrow z \Leftrightarrow p(z | x, y) = p(z | y) \Leftrightarrow I(x; z | y) = 0$
- **Data Processing Theorem:** if  $x \rightarrow y \rightarrow z$  then
  - $I(x; y) \geq I(x; z)$
  - $I(x; y) \geq I(x; y | z)$  can be false if not Markov
- **Fano's Inequality:** if  $x \rightarrow y \rightarrow \hat{x}$  then

$$p_e \geq \frac{H(x | y) - H(p_e)}{\log(|\mathcal{X}| - 1)} \geq \frac{H(x | y) - 1}{\log(|\mathcal{X}| - 1)} \geq \frac{H(x | y) - 1}{\log |\mathcal{X}|}$$

weaker but easier to use since independent of  $p_e$

# Lecture 8

---

- Weak Law of Large Numbers
- The Typical Set
  - Size and total probability
- Asymptotic Equipartition Principle

# Strong and Weak Typicality

---

$$\mathcal{X} = \{a, b, c, d\}, \mathbf{p} = [0.5 \ 0.25 \ 0.125 \ 0.125]$$

$$-\log \mathbf{p} = [1 \ 2 \ 3 \ 3] \Rightarrow H(\mathbf{p}) = 1.75 \text{ bits}$$

Sample eight i.i.d. values

- strongly typical  $\Rightarrow$  correct proportions

$$\text{aaaabbcd} \quad -\log p(\mathbf{x}) = 14 = 8 \times 1.75$$

- [weakly] typical  $\Rightarrow \log p(\mathbf{x}) = nH(\mathbf{x})$

$$\text{aabbbbbbb} \quad -\log p(\mathbf{x}) = 14 = 8 \times 1.75$$

- not typical at all  $\Rightarrow \log p(\mathbf{x}) \neq nH(\mathbf{x})$

$$\text{ddddddddd} \quad -\log p(\mathbf{x}) = 24$$

Strongly Typical  $\Rightarrow$  Typical

# Convergence of Random Numbers

---

- Convergence

$$X_n \xrightarrow[n \rightarrow \infty]{} y \Rightarrow \forall \varepsilon > 0, \exists m \text{ such that } \forall n > m, |X_n - y| < \varepsilon$$

Example:  $X_n = \pm 2^{-n}, \quad p = [1/2; 1/2]$

choose  $m = 1 - \log \varepsilon$

- Convergence in probability (weaker than convergence)

$$X_n \xrightarrow{\text{prob}} y \Rightarrow \forall \varepsilon > 0, \quad P(|X_n - y| > \varepsilon) \rightarrow 0$$

Example:  $x_n \in \{0; 1\}, \quad p = [1 - n^{-1}; n^{-1}]$

for any small  $\varepsilon$ ,  $p(|x_n| > \varepsilon) = n^{-1} \xrightarrow{n \rightarrow \infty} 0$

Note:  $y$  can be a constant or another random variable

# Weak law of Large Numbers

---

Given i.i.d.  $\{X_i\}$ , Cesáro mean  $s_n = \frac{1}{n} \sum_{i=1}^n X_i$

$$- E s_n = E X = \mu \quad \text{Var } s_n = n^{-1} \text{Var } X = n^{-1} \sigma^2$$

As  $n$  increases,  $\text{Var } s_n$  gets smaller and the values become clustered around the mean

WLLN:  $s_n \xrightarrow{\text{prob}} \mu$

$$\Leftrightarrow \forall \varepsilon > 0, \quad P(|s_n - \mu| > \varepsilon) \xrightarrow{n \rightarrow \infty} 0$$

The “strong law of large numbers” says that convergence is actually almost sure provided that  $X$  has finite variance

# Proof of WLLN

---

- Chebyshev's Inequality

$$\begin{aligned}\text{Var } y &= E(y - \mu)^2 = \sum_{y \in \mathcal{Y}} (y - \mu)^2 p(y) \\ &\geq \sum_{y: |y - \mu| > \varepsilon} (y - \mu)^2 p(y) \geq \sum_{y: |y - \mu| > \varepsilon} \varepsilon^2 p(y) = \varepsilon^2 p(|y - \mu| > \varepsilon)\end{aligned}$$

For any choice of  $\varepsilon$

- WLLN  $s_n = \frac{1}{n} \sum_{i=1}^n x_i$  where  $E x_i = \mu$  and  $\text{Var } x_i = \sigma^2$

$$\varepsilon^2 p(|s_n - \mu| > \varepsilon) \leq \text{Var } s_n = \frac{\sigma^2}{n} \xrightarrow{n \rightarrow \infty} 0$$

Hence  $s_n \xrightarrow{\text{prob}} \mu$

Actually true even if  $\sigma = \infty$

# Typical Set

$\mathbf{x}^n$  is the i.i.d. sequence  $\{x_i\}$  for  $1 \leq i \leq n$

- Prob of a particular sequence is  $p(\mathbf{x}) = \prod_{i=1}^n p(x_i)$
- $E - \log p(\mathbf{x}) = n E - \log p(x_i) = nH(X)$

– **Typical set:**  $T_{\varepsilon}^{(n)} = \left\{ \mathbf{x} \in \mathbf{X}^n : \left| -n^{-1} \log p(\mathbf{x}) - H(X) \right| < \varepsilon \right\}$

## Example:

- $x_i$  Bernoulli with  $p(x_i=1)=p$
- e.g.  $p([0 \ 1 \ 1 \ 0 \ 0 \ 0])=p^2(1-p)^4$
- For  $p=0.2$ ,  $H(X)=0.72$  bits
- **Red bar** shows  $T_{0.1}^{(n)}$

# Typical Set Frames

0000100001000000, 0000000010000000,  
 0000100001000000, 0000000010000000,

# Typical Set: Properties

1. Individual prob:  $\mathbf{x} \in T_\varepsilon^{(n)} \Rightarrow \log p(\mathbf{x}) = -nH(X) \pm n\varepsilon$
2. Total prob:  $p(\mathbf{x} \in T_\varepsilon^{(n)}) > 1 - \varepsilon$  for  $n > N_\varepsilon$
3. Size:  $(1 - \varepsilon)2^{n(H(X) - \varepsilon)} < |T_\varepsilon^{(n)}| \leq 2^{n(H(X) + \varepsilon)}$

**Proof 2:**  $-n^{-1} \log p(\mathbf{x}) = n^{-1} \sum_{i=1}^n -\log p(x_i) \xrightarrow{\text{prob}} E -\log p(x_i) = H(X)$

Hence  $\forall \varepsilon > 0 \exists N_\varepsilon$  s.t.  $\forall n > N_\varepsilon \quad p(|-n^{-1} \log p(\mathbf{x}) - H(X)| > \varepsilon) < \varepsilon$

**Proof 3a:** f.l.e.  $n$ ,  $1 - \varepsilon < p(\mathbf{x} \in T_\varepsilon^{(n)}) \leq \sum_{\mathbf{x} \in T_\varepsilon^{(n)}} 2^{-n(H(X) - \varepsilon)} = 2^{-n(H(X) - \varepsilon)} |T_\varepsilon^{(n)}|$

**Proof 3b:**  $1 = \sum_{\mathbf{x}} p(\mathbf{x}) \geq \sum_{\mathbf{x} \in T_\varepsilon^{(n)}} p(\mathbf{x}) \geq \sum_{\mathbf{x} \in T_\varepsilon^{(n)}} 2^{-n(H(X) + \varepsilon)} = 2^{-n(H(X) + \varepsilon)} |T_\varepsilon^{(n)}|$

# Asymptotic Equipartition Principle

- for any  $\varepsilon$  and for  $n > N_\varepsilon$   
 “Almost all events are almost equally surprising”
- $p(\mathbf{x} \in T_\varepsilon^{(n)}) > 1 - \varepsilon$  and  $\log p(\mathbf{x}) = -nH(X) \pm n\varepsilon$

## Coding consequence

- $\mathbf{x} \in T_\varepsilon^{(n)}$  : ‘0’ + at most  $1 + n(H + \varepsilon)$  bits
- $\mathbf{x} \notin T_\varepsilon^{(n)}$  : ‘1’ + at most  $1 + n \log |\mathcal{X}|$  bits
- $L$  = Average code length  

$$\leq 2 + n(H + \varepsilon) + \varepsilon(n \log |\mathcal{X}|)$$

$$= n(H + \varepsilon + \varepsilon \log |\mathcal{X}| + 2n^{-1})$$

# Source Coding & Data Compression

---

For any choice of  $\delta > 0$ , we can, by choosing block size,  $n$ , large enough, do either of the following:

- make a lossless code using only  $H(x) + \delta$  bits per symbol on average: 
$$L \leq n(H + \varepsilon + \varepsilon \log |\mathcal{X}| + 2n^{-1})$$
- make a code with an error probability  $< \varepsilon$  using  $H(x) + \delta$  bits for each symbol
  - just code  $T_\varepsilon$  using  $n(H + \varepsilon + n^{-1})$  bits and use a random wrong code if  $\mathbf{x} \notin T_\varepsilon$

# What $N_\varepsilon$ ensures that $p(\mathbf{x} \in T_\varepsilon^{(n)}) > 1 - \varepsilon$ ?

---

From WLLN, if  $\text{Var}(-\log p(x_i)) = \sigma^2$  then for any  $n$  and  $\varepsilon$

$$\varepsilon^2 p\left(\left|\frac{1}{n} \sum_{i=1}^n -\log p(x_i) - H(X)\right| > \varepsilon\right) \leq \frac{\sigma^2}{n} \Rightarrow p(\mathbf{x} \notin T_\varepsilon^{(n)}) \leq \frac{\sigma^2}{n\varepsilon^2} \quad \text{Chebyshev}$$

Choose  $N_\varepsilon = \sigma^2 \varepsilon^{-3} \Rightarrow p(\mathbf{x} \in T_\varepsilon^{(n)}) > 1 - \varepsilon$

$N_\varepsilon$  increases rapidly for small  $\varepsilon$

For this choice of  $N_\varepsilon$ , if  $\mathbf{x} \in T_\varepsilon^{(n)}$

$$\log p(\mathbf{x}) = -nH(X) \pm n\varepsilon = -nH(X) \pm \sigma^2 \varepsilon^{-2}$$

So within  $T_\varepsilon^{(n)}$ ,  $p(\mathbf{x})$  can vary by a factor of  $2^{2\sigma^2 \varepsilon^{-2}}$

Within the Typical Set,  $p(\mathbf{x})$  can actually vary a great deal when  $\varepsilon$  is small

# Smallest high-probability Set

---

$T_\varepsilon^{(n)}$  is a small subset of  $\mathcal{X}^n$  containing most of the probability mass. Can you get even smaller ?

For any  $0 < \varepsilon < 1$ , choose  $N_0 = -\varepsilon^{-1} \log \varepsilon$ , then for any  $n > \max(N_0, N_\varepsilon)$  and any subset  $S^{(n)}$  satisfying  $|S^{(n)}| < 2^{n(H(X) - 2\varepsilon)}$

$$\begin{aligned}
 p(\mathbf{x} \in S^{(n)}) &= p(\mathbf{x} \in S^{(n)} \cap T_\varepsilon^{(n)}) + p(\mathbf{x} \in S^{(n)} \cap \overline{T_\varepsilon^{(n)}}) \\
 &< |S^{(n)}| \max_{\mathbf{x} \in T_\varepsilon^{(n)}} p(\mathbf{x}) + p(\mathbf{x} \in \overline{T_\varepsilon^{(n)}}) \\
 &< 2^{n(H - 2\varepsilon)} 2^{-n(H - \varepsilon)} + \varepsilon && \text{for } n > N_\varepsilon \\
 &= 2^{-n\varepsilon} + \varepsilon < 2\varepsilon && \text{for } n > N_0, \quad 2^{-n\varepsilon} < 2^{\log \varepsilon} = \varepsilon
 \end{aligned}$$

Answer: No

# Summary

---

- Typical Set
  - Individual Prob  $\mathbf{x} \in T_\varepsilon^{(n)} \Rightarrow \log p(\mathbf{x}) = -nH(X) \pm n\varepsilon$
  - Total Prob  $p(\mathbf{x} \in T_\varepsilon^{(n)}) > 1 - \varepsilon$  for  $n > N_\varepsilon$
  - Size  $(1 - \varepsilon)2^{n(H(X) - \varepsilon)} < |T_\varepsilon^{(n)}| \leq 2^{n(H(X) + \varepsilon)}$
- No other high probability set can be much smaller than  $T_\varepsilon^{(n)}$
- Asymptotic Equipartition Principle
  - Almost all event sequences are equally surprising

# Lecture 9

---

- Source and Channel Coding
- Discrete Memoryless Channels
  - Symmetric Channels
  - Channel capacity
    - Binary Symmetric Channel
    - Binary Erasure Channel
    - Asymmetric Channel

# Source and Channel Coding

---

- Source Coding
  - Compresses the data to remove redundancy
- Channel Coding
  - Adds redundancy to protect against channel errors

# Discrete Memoryless Channel

---

- Input:  $x \in \mathcal{X}$ , Output  $y \in \mathcal{Y}$

- Time-Invariant Transition-Probability Matrix

$$(\mathbf{Q}_{\mathcal{Y}|\mathcal{X}})_{i,j} = p(\mathcal{Y} = y_j \mid \mathcal{X} = x_i)$$

– Hence  $\mathbf{p}_{\mathcal{Y}} = \mathbf{Q}_{\mathcal{Y}|\mathcal{X}}^T \mathbf{p}_{\mathcal{X}}$

–  $\mathbf{Q}$ : each row sum = 1, average column sum =  $|\mathcal{X}| |\mathcal{Y}|^{-1}$

- Memoryless:  $\mathbf{p}(\mathcal{Y}_n | \mathcal{X}_{1:n}, \mathcal{Y}_{1:n-1}) = \mathbf{p}(\mathcal{Y}_n | \mathcal{X}_n)$
- DMC = Discrete Memoryless Channel

# Binary Channels

- Binary Symmetric Channel**

$$\begin{pmatrix} 1-f & f \\ f & 1-f \end{pmatrix}$$

–  $\mathbf{X} = [0 \ 1]$ ,  $\mathbf{Y} = [0 \ 1]$
- Binary Erasure Channel**

$$\begin{pmatrix} 1-f & f & 0 \\ 0 & f & 1-f \end{pmatrix}$$

–  $\mathbf{X} = [0 \ 1]$ ,  $\mathbf{Y} = [0 \ ? \ 1]$
- Z Channel**

$$\begin{pmatrix} 1 & 0 \\ f & 1-f \end{pmatrix}$$

–  $\mathbf{X} = [0 \ 1]$ ,  $\mathbf{Y} = [0 \ 1]$

Symmetric: rows are permutations of each other; columns are permutations of each other

Weakly Symmetric: rows are permutations of each other; columns have the same sum

# Weakly Symmetric Channels

---

## Weakly Symmetric:

1. All columns of  $\mathbf{Q}$  have the same sum  $= |\mathcal{X}||\mathcal{Y}|^{-1}$

- If  $x$  is uniform (i.e.  $p(x) = |\mathcal{X}|^{-1}$ ) then  $y$  is uniform

$$p(y) = \sum_{x \in \mathcal{X}} p(y|x)p(x) = |\mathcal{X}|^{-1} \sum_{x \in \mathcal{X}} p(y|x) = |\mathcal{X}|^{-1} \times |\mathcal{X}||\mathcal{Y}|^{-1} = |\mathcal{Y}|^{-1}$$

2. All rows are permutations of each other

- Each row of  $\mathbf{Q}$  has the same entropy so

$$H(\mathcal{Y} | \mathcal{X}) = \sum_{x \in \mathcal{X}} p(x)H(\mathcal{Y} | \mathcal{X} = x) = H(\mathbf{Q}_{1,:}) \sum_{x \in \mathcal{X}} p(x) = H(\mathbf{Q}_{1,:})$$

where  $\mathbf{Q}_{1,:}$  is the entropy of the first (or any other) row of the  $\mathbf{Q}$  matrix

Symmetric: 1. All rows are permutations of each other  
2. All columns are permutations of each other

Symmetric  $\Rightarrow$  weakly symmetric

# Channel Capacity

- **Capacity** of a DMC channel:  $C = \max_{\mathbf{p}_x} I(x; y)$ 
  - Maximum is over all possible input distributions  $\mathbf{p}_x$
  - $\exists$  only one maximum since  $I(x; y)$  is concave in  $\mathbf{p}_x$  for fixed  $\mathbf{p}_{y|x}$  ♦
  - We want to find the  $\mathbf{p}_x$  that maximizes  $I(x; y)$
  - Limits on  $C$ :

$$0 \leq C \leq \min(H(x), H(y)) \leq \min(\log|\mathcal{X}|, \log|\mathcal{Y}|)$$

- **Capacity** for  $n$  uses of channel:

$$C^{(n)} = \frac{1}{n} \max_{\mathbf{p}_{x_{1:n}}} I(x_{1:n}; y_{1:n})$$

♦ = proved in two pages time

# Mutual Information Plot

Binary Symmetric Channel  
Bernoulli Input

$$I(x; y) = H(y) - H(x | y) \\ = H(f - 2pf + p) - H(f)$$

Channel Error Prob ( $f$ )

# Mutual Information Concave in $\mathbf{p}_X$

Mutual Information  $I(x; y)$  is **concave** in  $\mathbf{p}_X$  for fixed  $\mathbf{p}_{Y|X}$

**Proof:** Let  $u$  and  $v$  have prob mass vectors  $\mathbf{u}$  and  $\mathbf{v}$

- Define  $z$ : bernoulli random variable with  $p(1) = \lambda$
- Let  $x = u$  if  $z=1$  and  $x=v$  if  $z=0 \Rightarrow \mathbf{p}_x = \lambda\mathbf{u} + (1-\lambda)\mathbf{v}$

$$I(x, z; y) = I(x; y) + I(z; y | x) = I(z; y) + I(x; y | z)$$

but  $I(z; y | x) = H(y | x) - H(y | x, z) = 0$  so

$$I(x; y) \geq I(x; y | z)$$

$$= \lambda I(x; y | z = 1) + (1 - \lambda) I(x; y | z = 0)$$

$$= \lambda I(u; y) + (1 - \lambda) I(v; y)$$

● = Deterministic

Special Case:  $y=x \Rightarrow I(x; x) = H(x)$  is concave in  $\mathbf{p}_x$

# Mutual Information Convex in $\mathbf{p}_{Y|X}$

Mutual Information  $I(X;Y)$  is **convex** in  $\mathbf{p}_{Y|X}$  for fixed  $\mathbf{p}_X$

**Proof (b)** define  $u, v, x$  etc:

$$- \quad \mathbf{p}_{Y|X} = \lambda \mathbf{p}_{U|X} + (1-\lambda) \mathbf{p}_{V|X}$$

$$\begin{aligned} I(X;Y,Z) &= I(X;Y|Z) + I(X;Z) \\ &= I(X;Y) + I(X;Z|Y) \end{aligned}$$

but  $I(X;Z) = 0$  and  $I(X;Z|Y) \geq 0$  so

$$\begin{aligned} I(X;Y) &\leq I(X;Y|Z) \\ &= \lambda I(X;Y|Z=1) + (1-\lambda) I(X;Y|Z=0) \\ &= \lambda I(X;U) + (1-\lambda) I(X;V) \end{aligned}$$

● = Deterministic

# $n$ -use Channel Capacity

---

For Discrete Memoryless Channel:

$$\begin{aligned} I(\mathbf{x}_{1:n}; \mathbf{y}_{1:n}) &= H(\mathbf{y}_{1:n}) - H(\mathbf{y}_{1:n} | \mathbf{x}_{1:n}) \\ &= \sum_{i=1}^n H(y_i | \mathbf{y}_{1:i-1}) - \sum_{i=1}^n H(y_i | x_i) && \text{Chain; Memoryless} \\ &\leq \sum_{i=1}^n H(y_i) - \sum_{i=1}^n H(y_i | x_i) = \sum_{i=1}^n I(x_i; y_i) && \begin{array}{l} \text{Conditioning} \\ \text{Reduces} \\ \text{Entropy} \end{array} \end{aligned}$$

with equality if  $x_i$  are independent  $\Rightarrow y_i$  are independent

We can maximize  $I(\mathbf{x}; \mathbf{y})$  by maximizing each  $I(x_i; y_i)$  independently and taking  $x_i$  to be i.i.d.

- We will concentrate on maximizing  $I(x; y)$  for a single channel use

# Capacity of Symmetric Channel

If channel is **weakly symmetric**:

$$I(x; y) = H(y) - H(y | x) = H(y) - H(\mathbf{Q}_{1,:}) \leq \log |\mathcal{Y}| - H(\mathbf{Q}_{1,:})$$

with equality iff input distribution is uniform

$\therefore$  Information Capacity of a WS channel is  $\log|\mathcal{Y}| - H(\mathbf{Q}_{1,:})$

For a **binary symmetric channel (BSC)**:

- $|\mathcal{Y}| = 2$
- $H(\mathbf{Q}_{1,:}) = H(f)$
- $I(x; y) \leq 1 - H(f)$

$\therefore$  Information Capacity of a BSC is  $1 - H(f)$

# Binary Erasure Channel (BEC)

$$\begin{pmatrix} 1-f & f & 0 \\ 0 & f & 1-f \end{pmatrix}$$

$$I(x; y) = H(x) - H(x | y)$$

$$= H(x) - p(y = 0) \times 0 - p(y = ?) H(x) - p(y = 1) \times 0$$

$$= H(x) - H(x) f$$

$H(x | y) = 0$  when  $y=0$  or  $y=1$

$$= (1-f) H(x)$$

$$\leq 1-f$$

since max value of  $H(x) = 1$   
with equality when  $x$  is uniform

since a fraction  $f$  of the bits are lost, the capacity is only  $1-f$   
and this is achieved when  $x$  is uniform

# Asymmetric Channel Capacity

Let  $\mathbf{p}_x = [a \ a \ 1-2a]^T \Rightarrow \mathbf{p}_y = \mathbf{Q}^T \mathbf{p}_x = \mathbf{p}_x$

$$H(y) = -2a \log a - (1-2a) \log(1-2a)$$

$$H(y|x) = 2aH(f) + (1-2a)H(1) = 2aH(f)$$

To find  $C$ , maximize  $I(x;y) = H(y) - H(y|x)$

$$I = -2a \log a - (1-2a) \log(1-2a) - 2aH(f)$$

$$\frac{dI}{da} = -2 \log e - 2 \log a + 2 \log e + 2 \log(1-2a) - 2H(f) = 0$$

$$\mathbf{Q} = \begin{pmatrix} 1-f & f & 0 \\ f & 1-f & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

$$\log \frac{1-2a}{a} = \log(a^{-1} - 2) = H(f) \Rightarrow a = (2 + 2^{H(f)})^{-1}$$

$$\Rightarrow C = -2a \log(a 2^{H(f)}) - (1-2a) \log(1-2a) = -\log(1-2a)$$

Note:

$$d(\log x) = x^{-1} \log e$$

Examples:  $f=0 \Rightarrow H(f)=0 \Rightarrow a=1/3 \Rightarrow C=\log 3 = 1.585$  bits/use

$f=1/2 \Rightarrow H(f)=1 \Rightarrow a=1/4 \Rightarrow C=\log 2 = 1$  bits/use

# Lecture 10

---

- Jointly Typical Sets
- Joint AEP
- Channel Coding Theorem
  - Random Coding
  - Jointly typical decoding

# Significance of Mutual Information

- Consider blocks of  $n$  symbols:

- An average input sequence  $x_{1:n}$  corresponds to about  $2^{nH(y|x)}$  typical output sequences
- There are a total of  $2^{nH(y)}$  typical output sequences
- For nearly error free transmission, we select a number of input sequences whose corresponding sets of output sequences hardly overlap
- The maximum number of distinct sets of output sequences is  $2^{n(H(y) - H(y|x))} = 2^{nI(y;x)}$

Channel Coding Theorem: for large  $n$  can transmit at any rate  $< C$  with negligible errors

# Jointly Typical Set

---

$\mathbf{x}\mathbf{y}^n$  is the i.i.d. sequence  $\{x_i, y_i\}$  for  $1 \leq i \leq n$

- Prob of a particular sequence is  $p(\mathbf{x}, \mathbf{y}) = \prod_{i=1}^n p(x_i, y_i)$
- $E - \log p(\mathbf{x}, \mathbf{y}) = n E - \log p(x_i, y_i) = nH(X, Y)$

– Jointly Typical set:

$$J_{\varepsilon}^{(n)} = \left\{ \mathbf{x}, \mathbf{y} \in \mathbf{x}\mathbf{y}^n : \begin{aligned} & \left| -n^{-1} \log p(\mathbf{x}) - H(X) \right| < \varepsilon, \\ & \left| -n^{-1} \log p(\mathbf{y}) - H(Y) \right| < \varepsilon, \\ & \left| -n^{-1} \log p(\mathbf{x}, \mathbf{y}) - H(X, Y) \right| < \varepsilon \end{aligned} \right\}$$

# Jointly Typical Example

## Binary Symmetric Channel

$$f = 0.2, \quad \mathbf{p}_x = (0.75 \quad 0.25)^T$$

$$\mathbf{p}_y = (0.65 \quad 0.35)^T, \quad \mathbf{P}_{xy} = \begin{pmatrix} 0.6 & 0.15 \\ 0.05 & 0.2 \end{pmatrix}$$

Jointly Typical example (for any  $\varepsilon$ ):

$\mathbf{x} = 1 \ 1 \ 1 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0$

$\mathbf{y} = 1 \ 1 \ 1 \ 1 \ 0 \ 1 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0$

all combinations of  $x$  and  $y$  have exactly the right frequencies

# Jointly Typical Diagram

Each point defines both an  $\mathbf{x}$  sequence and a  $\mathbf{y}$  sequence

Dots represent jointly typical pairs  $(\mathbf{x}, \mathbf{y})$

Inner rectangle represents pairs that are typical in  $\mathbf{x}$  or  $\mathbf{y}$  but not necessarily jointly typical

- There are about  $2^{nH(\mathbf{x})}$  typical  $\mathbf{x}$ 's in all
- Each typical  $\mathbf{y}$  is jointly typical with about  $2^{nH(\mathbf{x}|\mathbf{y})}$  of these typical  $\mathbf{x}$ 's
- The jointly typical pairs are a fraction  $2^{-nI(\mathbf{x}; \mathbf{y})}$  of the inner rectangle
- Channel Code: choose  $\mathbf{x}$ 's whose J.T.  $\mathbf{y}$ 's don't overlap; use J.T. for decoding

# Joint Typical Set Properties

---

1. Indiv Prob:  $\mathbf{x}, \mathbf{y} \in J_\varepsilon^{(n)} \Rightarrow \log p(\mathbf{x}, \mathbf{y}) = -nH(X, Y) \pm n\varepsilon$
2. Total Prob:  $p(\mathbf{x}, \mathbf{y} \in J_\varepsilon^{(n)}) > 1 - \varepsilon$  for  $n > N_\varepsilon$
3. Size:  $(1 - \varepsilon)2^{n(H(X, Y) - \varepsilon)} < |J_\varepsilon^{(n)}| \leq 2^{n(H(X, Y) + \varepsilon)}$

**Proof 2:** (use weak law of large numbers)

Choose  $N_1$  such that  $\forall n > N_1, \quad p\left(\left| -n^{-1} \log p(\mathbf{x}) - H(X) \right| > \varepsilon\right) < \frac{\varepsilon}{3}$

Similarly choose  $N_2, N_3$  for other conditions and set  $N_\varepsilon = \max(N_1, N_2, N_3)$

**Proof 3:**  $1 - \varepsilon < \sum_{\mathbf{x}, \mathbf{y} \in J_\varepsilon^{(n)}} p(\mathbf{x}, \mathbf{y}) \leq |J_\varepsilon^{(n)}| \max_{\mathbf{x}, \mathbf{y} \in J_\varepsilon^{(n)}} p(\mathbf{x}, \mathbf{y}) = |J_\varepsilon^{(n)}| 2^{-n(H(X, Y) - \varepsilon)} \quad n > N_\varepsilon$

$1 \geq \sum_{\mathbf{x}, \mathbf{y} \in J_\varepsilon^{(n)}} p(\mathbf{x}, \mathbf{y}) \geq |J_\varepsilon^{(n)}| \min_{\mathbf{x}, \mathbf{y} \in J_\varepsilon^{(n)}} p(\mathbf{x}, \mathbf{y}) = |J_\varepsilon^{(n)}| 2^{-n(H(X, Y) + \varepsilon)} \quad \forall n$

# Joint AEP

---

If  $\mathbf{p}_{x'} = \mathbf{p}_x$  and  $\mathbf{p}_{y'} = \mathbf{p}_y$  with  $x'$  and  $y'$  independent:

$$(1 - \varepsilon)2^{-n(I(x,y)+3\varepsilon)} \leq p(\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}) \leq 2^{-n(I(x,y)-3\varepsilon)} \text{ for } n > N_\varepsilon$$

**Proof:**  $|J| \times (\text{Min Prob}) \leq \text{Total Prob} \leq |J| \times (\text{Max Prob})$

$$p(\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}) = \sum_{\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}} p(\mathbf{x}', \mathbf{y}') = \sum_{\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}} p(\mathbf{x}') p(\mathbf{y}')$$

$$\begin{aligned} p(\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}) &\leq |J_\varepsilon^{(n)}| \max_{\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}} p(\mathbf{x}') p(\mathbf{y}') \\ &\leq 2^{n(H(x,y)+\varepsilon)} 2^{-n(H(x)-\varepsilon)} 2^{-n(H(y)-\varepsilon)} = 2^{-n(I(x;y)-3\varepsilon)} \end{aligned}$$

$$\begin{aligned} p(\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}) &\geq |J_\varepsilon^{(n)}| \min_{\mathbf{x}', \mathbf{y}' \in J_\varepsilon^{(n)}} p(\mathbf{x}') p(\mathbf{y}') \\ &\geq (1 - \varepsilon) 2^{-n(I(x;y)+3\varepsilon)} \text{ for } n > N_\varepsilon \end{aligned}$$

# Channel Codes

- Assume Discrete Memoryless Channel with known  $\mathbf{Q}_{y|x}$
- An  $(M, n)$  code is
  - A fixed set of  $M$  codewords  $\mathbf{x}(w) \in \mathcal{X}^n$  for  $w=1:M$
  - A deterministic decoder  $g(\mathbf{y}) \in 1:M$
- Error probability  $\lambda_w = p(g(\mathbf{y}(w)) \neq w) = \sum_{\mathbf{y} \in \mathcal{Y}^n} p(\mathbf{y} | \mathbf{x}(w)) \delta_{g(\mathbf{y}) \neq w}$ 
  - Maximum Error Probability  $\lambda^{(n)} = \max_{1 \leq w \leq M} \lambda_w$
  - Average Error probability  $P_e^{(n)} = \frac{1}{M} \sum_{w=1}^M \lambda_w$

$\delta_C = 1$  if  $C$  is true or 0 if it is false

# Achievable Code Rates

---

- The **rate** of an  $(M, n)$  code:  $R = (\log M)/n$  bits/transmission
- A rate,  $R$ , is **achievable** if
  - $\exists$  a sequence of  $(\lceil 2^{nR} \rceil, n)$  codes for  $n=1, 2, \dots$
  - max prob of error  $\lambda^{(n)} \rightarrow 0$  as  $n \rightarrow \infty$
  - **Note:** we will normally write  $(2^{nR}, n)$  to mean  $(\lceil 2^{nR} \rceil, n)$
- The **capacity** of a DMC is the sup of all achievable rates
- Max error probability for a code is hard to determine
  - **Shannon's idea:** consider a **randomly** chosen code
  - show the expected **average** error probability is small
  - Show this means  $\exists$  at least one code with small **max** error prob
  - Sadly it doesn't tell you how to find the code

# Channel Coding Theorem

- A rate  $R$  is achievable if  $R < C$  and not achievable if  $R > C$ 
  - If  $R < C$ ,  $\exists$  a sequence of  $(2^{nR}, n)$  codes with max prob of error  $\lambda^{(n)} \rightarrow 0$  as  $n \rightarrow \infty$
  - Any sequence of  $(2^{nR}, n)$  codes with max prob of error  $\lambda^{(n)} \rightarrow 0$  as  $n \rightarrow \infty$  must have  $R \leq C$

## A very counterintuitive result:

Despite channel errors you can get arbitrarily low bit error rates provided that  $R < C$

# Lecture 11

---

- Channel Coding Theorem

# Channel Coding Principle

- Consider blocks of  $n$  symbols:

- An average input sequence  $x_{1:n}$  corresponds to about  $2^{nH(y|x)}$  typical output sequences
- **Random Codes:** Choose  $2^{nR}$  random code vectors  $\mathbf{x}(w)$ 
  - their typical output sequences are unlikely to overlap much.
- **Joint Typical Decoding:** A received vector  $\mathbf{y}$  is very likely to be in the typical output set of the transmitted  $\mathbf{x}(w)$  and no others. Decode as this  $w$ .

Channel Coding Theorem: for large  $n$ , can transmit at any rate  $R < C$  with negligible errors

# Random $(2^{nR}, n)$ Code

---

- Choose  $\varepsilon \approx$  error prob, joint typicality  $\Rightarrow N_\varepsilon$ , choose  $n > N_\varepsilon$
- Choose  $\mathbf{p}_x$  so that  $I(x; y) = C$ , the information capacity
- Use  $\mathbf{p}_x$  to choose a code  $\mathcal{C}$  with random  $\mathbf{x}(w) \in \mathcal{X}^n$ ,  $w = 1:2^{nR}$ 
  - the receiver knows this code and also the transition matrix  $\mathbf{Q}$
- Assume (for now) the message  $W \in 1:2^{nR}$  is uniformly distributed
- If received value is  $\mathbf{y}$ ; decode the message by seeing how many  $\mathbf{x}(w)$ 's are jointly typical with  $\mathbf{y}$ 
  - if  $\mathbf{x}(k)$  is the only one then  $k$  is the decoded message
  - if there are 0 or  $\geq 2$  possible  $k$ 's then 1 is the decoded message
  - we calculate error probability averaged over all  $\mathcal{C}$  and all  $W$

$$p(\mathcal{E}) = \sum_{\mathcal{C}} p(\mathcal{C}) 2^{-nR} \sum_{w=1}^{2^{nR}} \lambda_w(\mathcal{C}) = 2^{-nR} \sum_{w=1}^{2^{nR}} \sum_{\mathcal{C}} p(\mathcal{C}) \lambda_w(\mathcal{C}) \stackrel{(a)}{=} \sum_{\mathcal{C}} p(\mathcal{C}) \lambda_1(\mathcal{C}) = p(\mathcal{E} | W = 1)$$

(a) since error averaged over all possible codes is independent of  $w$

# Channel Coding Principle

- Assume we transmit  $\mathbf{x}(1)$  and receive  $\mathbf{y}$
- Define the events  $e_w = \{\mathbf{x}(w), \mathbf{y} \in J_{\varepsilon}^{(n)}\}$  for  $w \in 1:2^{nR}$

- We have an error if either  $e_1$  false or  $e_w$  true for  $w \geq 2$
- The  $\mathbf{x}(w)$  for  $w \neq 1$  are independent of  $\mathbf{x}(1)$  and hence also independent of  $\mathbf{y}$ . So  $p(e_w \text{ true}) < 2^{-n(I(\mathbf{x}, \mathbf{y}) - 3\varepsilon)}$  for any  $w \neq 1$

Joint AEP

# Error Probability for Random Code

- We transmit  $x(1)$ , receive  $y$  and decode using joint typicality
- We have an error if either  $e_1$  false or  $e_w$  true for  $w \geq 2$

$$\begin{aligned}
 p(\mathbf{e} | W=1) &= p(\bar{e}_1 \cup e_2 \cup e_3 \cup \dots \cup e_{2^{nR}}) \leq p(\bar{e}_1) + \sum_{w=2}^{2^{nR}} p(e_w) && p(A \cup B) \leq p(A) + p(B) \\
 &\leq \varepsilon + \sum_{i=2}^{2^{nR}} 2^{-n(I(X;Y)-3\varepsilon)} = \varepsilon + 2^{nR} 2^{-n(I(X;Y)-3\varepsilon)} && (1) \text{ Joint typicality} \\
 &\leq \varepsilon + 2^{-n(I(X;Y)-R-3\varepsilon)} \leq 2\varepsilon \text{ for } R < C - 3\varepsilon \text{ and } n > -\frac{\log \varepsilon}{C - R - 3\varepsilon} && (2) \text{ Joint AEP}
 \end{aligned}$$

- Since average of  $P_e^{(n)}$  over all codes is  $\leq 2\varepsilon$  there must be at least one code for which this is true: this code has  $2^{-nR} \sum_w \lambda_w \leq 2\varepsilon$  ◆
- Now throw away the worst half of the codewords; the remaining ones must all have  $\lambda_w \leq 4\varepsilon$ . The resultant code has rate  $R - n^{-1} \cong R$ . ◆

◆ = proved on next page

# Code Selection & Expurgation

---

- Since average of  $P_e^{(n)}$  over all codes is  $\leq 2\varepsilon$  there must be at least one code for which this is true.

Proof:

$$2\varepsilon \geq K^{-1} \sum_{i=1}^K P_{e,i}^{(n)} \geq K^{-1} \sum_{i=1}^K \min_i (P_{e,i}^{(n)}) = \min_i (P_{e,i}^{(n)})$$

$K$  = num of codes

- Expurgation: Throw away the worst half of the codewords; the remaining ones must all have  $\lambda_w \leq 4\varepsilon$ .

Proof: Assume  $\lambda_w$  are in descending order

$$\begin{aligned} 2\varepsilon &\geq M^{-1} \sum_{w=1}^M \lambda_w \geq M^{-1} \sum_{w=1}^{1/2 M} \lambda_w \geq M^{-1} \sum_{w=1}^{1/2 M} \lambda_{1/2 M} \geq 1/2 \lambda_{1/2 M} \\ \Rightarrow \lambda_{1/2 M} &\leq 4\varepsilon \Rightarrow \lambda_w \leq 4\varepsilon \quad \forall w > 1/2 M \end{aligned}$$

$$M' = 1/2 \times 2^{nR} \text{ messages in } n \text{ channel uses} \Rightarrow R' = n^{-1} \log M' = R - n^{-1}$$

# Summary of Procedure

---

- Given  $R' < C$ , **choose**  $\varepsilon < \frac{1}{4}(C - R')$  and set  $R = R' + \varepsilon \Rightarrow R < C - 3\varepsilon$
- **Set**  $n = \max\{N_\varepsilon, -(\log \varepsilon)/(C - R - 3\varepsilon), \varepsilon^{-1}\}$  see (a),(b),(c) below
- **Find** the optimum  $\mathbf{p}_X$  so that  $I(X; Y) = C$
- Choosing codewords randomly (using  $\mathbf{p}_X$ ) and using joint typicality as the decoder, **construct** codes with  $2^{nR}$  codewords (a)
- Since **average** of  $P_e^{(n)}$  over all codes is  $\leq 2\varepsilon$  there must be at least one code for which this is true. Find it by exhaustive search. (b)
- Throw away the worst half of the codewords. Now the **worst codeword** has an error prob  $\leq 4\varepsilon$  with rate  $R' = R - n^{-1} > R - \varepsilon$  (c)
- The resultant code transmits at a rate  $R'$  with an error probability that can be made as small as desired (but  $n$  unnecessarily large).

Note:  $\varepsilon$  determines both error probability and closeness to capacity

# Lecture 12

---

- Converse of Channel Coding Theorem
  - Cannot achieve  $R > C$
  - Minimum bit-error rate
- Capacity with feedback
  - no gain but simpler encode/decode
- Joint Source-Channel Coding
  - No point for a DMC

# Converse of Coding Theorem

- Fano's Inequality: if  $P_e^{(n)}$  is error prob when estimating  $w$  from  $\mathbf{y}$ ,

$$H(w | \mathbf{y}) \leq 1 + P_e^{(n)} \log |\mathbf{W}| = 1 + nRP_e^{(n)}$$

- Hence  $nR = H(w) = H(w | \mathbf{y}) + I(w; \mathbf{y})$

Definition of  $I$

$$\leq H(w | \mathbf{y}) + I(\mathbf{x}(w); \mathbf{y})$$

Markov :  $w \rightarrow \mathbf{x} \rightarrow \mathbf{y} \rightarrow \hat{w}$

$$\leq 1 + nRP_e^{(n)} + I(\mathbf{x}; \mathbf{y})$$

Fano

$$\leq 1 + nRP_e^{(n)} + nC$$

$n$ -use DMC capacity

$$\Rightarrow P_e^{(n)} \geq \frac{R - C - n^{-1}}{R} \xrightarrow{n \rightarrow \infty} \frac{R - C}{R}$$

- Hence for large  $n$ ,  $P_e^{(n)}$  has a lower bound of  $(R-C)/R$  if  $w$  equiprobable
  - If  $R > C$  was achievable for small  $n$ , it could be achieved also for large  $n$  by concatenation. Hence it cannot be achieved for any  $n$ .

# Minimum Bit-error Rate

Suppose

- $V_{1:nR}$  is i.i.d. bits with  $H(v_i)=1$
- The bit-error rate is  $P_b = E_i \{p(v_i \neq \hat{v}_i)\} \stackrel{\Delta}{=} E_i \{p(e_i)\}$

Then

$$\begin{aligned}
 nC &\stackrel{(a)}{\geq} I(X_{1:n}; Y_{1:n}) \stackrel{(b)}{\geq} I(V_{1:nR}; \hat{V}_{1:nR}) = H(V_{1:nR}) - H(V_{1:nR} | \hat{V}_{1:nR}) \\
 &= nR - \sum_{i=1}^{nR} H(v_i | \hat{V}_{1:nR}, v_{1:i-1}) \stackrel{(c)}{\geq} nR - \sum_{i=1}^{nR} H(v_i | \hat{v}_i) = nR \left(1 - E_i \{H(v_i | \hat{v}_i)\}\right) \\
 &\stackrel{(d)}{=} nR \left(1 - E_i \{H(e_i | \hat{v}_i)\}\right) \stackrel{(c)}{\geq} nR \left(1 - E_i \{H(e_i)\}\right) \stackrel{(e)}{\geq} nR \left(1 - H(E_i P_{b,i})\right) = nR(1 - H(P_b))
 \end{aligned}$$

Hence

$$R \leq C(1 - H(P_b))^{-1}$$

$$P_b \geq H^{-1}(1 - C/R)$$

(a) n-use capacity

(b) Data processing theorem

(c) Conditioning reduces entropy

(d)  $e_i = v_i \oplus \hat{v}_i$

(e) Jensen:  $E H(x) \leq H(E x)$

# Channel with Feedback

- Assume error-free feedback: does it increase capacity ?
- A  $(2^{nR}, n)$  **feedback code** is
  - A sequence of mappings  $x_i = x_i(w, y_{1:i-1})$  for  $i=1:n$
  - A decoding function  $\hat{w} = g(y_{1:n})$
- A rate  $R$  is **achievable** if  $\exists$  a sequence of  $(2^{nR}, n)$  feedback codes such that  $P_e^{(n)} = P(\hat{w} \neq w) \xrightarrow{n \rightarrow \infty} 0$
- **Feedback capacity**,  $C_{FB} \geq C$ , is the sup of achievable rates

# Capacity with Feedback

$$\begin{aligned}
 I(w; \mathbf{y}) &= H(\mathbf{y}) - H(\mathbf{y} | w) \\
 &= H(\mathbf{y}) - \sum_{i=1}^n H(y_i | y_{1:i-1}, w) \\
 &= H(\mathbf{y}) - \sum_{i=1}^n H(y_i | y_{1:i-1}, w, x_i) && \text{since } x_i = x_i(w, y_{1:i-1}) \\
 &= H(\mathbf{y}) - \sum_{i=1}^n H(y_i | x_i) && \text{since } y_i \text{ only directly depends on } x_i \\
 &\leq \sum_{i=1}^n H(y_i) - \sum_{i=1}^n H(y_i | x_i) = \sum_{i=1}^n I(x_i; y_i) \leq nC && \text{cond reduces ent}
 \end{aligned}$$

Hence

$$nR = H(w) = H(w | \mathbf{y}) + I(w; \mathbf{y}) \leq 1 + nRP_e^{(n)} + nC \quad \text{Fano}$$

$$\Rightarrow P_e^{(n)} \geq \frac{R - C - n^{-1}}{R}$$

The DMC does not benefit from feedback:  $C_{FB} = C$

# Example: BEC with feedback

---

- Capacity is  $1-f$
- Encode algorithm
  - If  $y_i=?$ , retransmit bit  $i$
  - Average number of transmissions per bit:

$$1 + f + f^2 + \dots = \frac{1}{1-f}$$

- Average number of bits per transmission =  $1-f$
- Capacity unchanged but encode/decode algorithm much simpler.

# Joint Source-Channel Coding

- Assume  $V_i$  satisfies AEP and  $|\mathcal{V}| < \infty$ 
  - Examples: i.i.d.; markov; stationary ergodic
- Capacity of DMC channel is  $C$ 
  - if time-varying:  $C = \lim_{n \rightarrow \infty} n^{-1} I(\mathbf{x}; \mathbf{y})$
- Joint Source Channel Coding Theorem: ◆

$\exists$  codes with  $P_e^{(n)} = P(\hat{V}_{1:n} \neq V_{1:n}) \xrightarrow{n \rightarrow \infty} 0$  iff  $H(\mathcal{V}) < C$

  - errors arise from incorrect (i) encoding of  $V$  or (ii) decoding of  $Y$
- Important result: source coding and channel coding might as well be done separately since same capacity

◆ = proved on next page

# Source-Channel Proof ( $\Leftarrow$ )

---

- For  $n > N_\varepsilon$  there are only  $2^{n(H(\mathbf{V})+\varepsilon)}$   $\mathbf{v}$ 's in the typical set: encode using  $n(H(\mathbf{V})+\varepsilon)$  bits
  - encoder error  $< \varepsilon$
- Transmit with error prob less than  $\varepsilon$  so long as  $H(\mathbf{V}) + \varepsilon < C$
- Total error prob  $< 2\varepsilon$

# Source-Channel Proof ( $\Rightarrow$ )

**Fano's Inequality:**  $H(\mathbf{v} | \hat{\mathbf{v}}) \leq 1 + P_e^{(n)} n \log |\mathcal{V}|$

$$H(\mathbf{V}) \leq n^{-1} H(v_{1:n})$$

entropy rate of stationary process

$$= n^{-1} H(v_{1:n} | \hat{v}_{1:n}) + n^{-1} I(v_{1:n}; \hat{v}_{1:n})$$

definition of  $I$

$$\leq n^{-1} (1 + P_e^{(n)} n \log |\mathcal{V}|) + n^{-1} I(x_{1:n}; y_{1:n})$$

Fano + Data Proc Inequ

$$\leq n^{-1} + P_e^{(n)} \log |\mathcal{V}| + C$$

Memoryless channel

**Let**  $n \rightarrow \infty \Rightarrow P_e^{(n)} \rightarrow 0 \Rightarrow H(\mathbf{V}) \leq C$

# Separation Theorem

---

- For a (time-varying) DMC we can design the source encoder and the channel coder separately and still get optimum performance
- Not true for
  - Correlated Channel and Source
  - Multiple access with correlated sources
    - Multiple sources transmitting to a single receiver
  - Broadcasting channels
    - one source transmitting possibly different information to multiple receivers

# Lecture 13

---

- Continuous Random Variables
- Differential Entropy
  - can be negative
  - not a measure of the information in  $x$
  - coordinate-dependent
- Maximum entropy distributions
  - Uniform over a finite range
  - Gaussian if a constant variance

# Continuous Random Variables

---

## Changing Variables

- pdf:  $f_x(x)$       CDF:  $F_x(x) = \int_{-\infty}^x f_x(t)dt$
- For  $g(x)$  monotonic:  $y = g(x) \Leftrightarrow x = g^{-1}(y)$   
 $F_y(y) = F_x(g^{-1}(y))$  or  $1 - F_x(g^{-1}(y))$       according to slope of  $g(x)$   
 $f_y(y) = \frac{dF_y(y)}{dy} = f_x(g^{-1}(y)) \left| \frac{dg^{-1}(y)}{dy} \right| = f_x(x) \left| \frac{dx}{dy} \right|$  where  $x = g^{-1}(y)$

- Examples:

Suppose  $f_x(x) = 0.5$  for  $x \in (0,2) \Rightarrow F_x(x) = 0.5x$

(a)  $y = 4x \Rightarrow x = 0.25y \Rightarrow f_y(y) = 0.5 \times 0.25 = 0.125$  for  $y \in (0,8)$

(b)  $z = x^4 \Rightarrow x = z^{1/4} \Rightarrow f_z(z) = 0.5 \times \frac{1}{4} z^{-3/4} = 0.125 z^{-3/4}$  for  $z \in (0,16)$

# Joint Distributions Distributions

Joint pdf:  $f_{x,y}(x,y)$

Marginal pdf:  $f_x(x) = \int_{-\infty}^{\infty} f_{x,y}(x,y) dy$

Independence:  $\Leftrightarrow f_{x,y}(x,y) = f_x(x)f_y(y)$

Conditional pdf:  $f_{x|y}(x) = \frac{f_{x,y}(x,y)}{f_y(y)}$

Example:

$$f_{x,y} = 1 \text{ for } y \in (0,1), x \in (y, y+1)$$

$$f_{x|y} = 1 \text{ for } x \in (y, y+1)$$

$$f_{y|x} = \frac{1}{\min(x, 1-x)} \text{ for } y \in (\max(0, x-1), \min(x, 1))$$

# Quantised Random Variables

---

- Given a continuous pdf  $f(x)$ , we divide the range of  $x$  into bins of width  $\Delta$ 
  - For each  $i$ ,  $\exists x_i$  with  $f(x_i)\Delta = \int_{i\Delta}^{(i+1)\Delta} f(x)dx$  mean value theorem
- Define a discrete random variable  $Y$ 
  - $\mathcal{Y} = \{x_i\}$  and  $p_Y = \{f(x_i)\Delta\}$
  - Scaled, quantised version of  $f(x)$  with slightly unevenly spaced  $x_i$
- $$H(Y) = -\sum f(x_i)\Delta \log(f(x_i)\Delta)$$

$$= -\log \Delta - \sum f(x_i) \log(f(x_i))\Delta$$

$$\xrightarrow{\Delta \rightarrow 0} -\log \Delta - \int_{-\infty}^{\infty} f(x) \log f(x) dx = -\log \Delta + h(X)$$
- Differential entropy:  $h(X) = -\int_{-\infty}^{\infty} f_X(x) \log f_X(x) dx$

# Differential Entropy

---

**Differential Entropy:** 
$$h(x) \stackrel{\Delta}{=} - \int_{-\infty}^{\infty} f_x(x) \log f_x(x) dx = E - \log f_x(x)$$

## Bad News:

- $h(x)$  does not give the amount of information in  $x$
- $h(x)$  is not necessarily positive
- $h(x)$  changes with a change of coordinate system

## Good News:

- $h_1(x) - h_2(x)$  does compare the uncertainty of two continuous random variables **provided they are quantised to the same precision**
- Relative Entropy and Mutual Information still work fine
- If the range of  $x$  is normalized to 1 and then  $x$  is quantised to  $n$  bits, the entropy of the resultant discrete random variable is approximately  $h(x) + n$

# Differential Entropy Examples

---

- **Uniform Distribution:**  $X \sim U(a, b)$ 
  - $f(x) = (b-a)^{-1}$  for  $x \in (a, b)$  and  $f(x) = 0$  elsewhere
  - $h(X) = -\int_a^b (b-a)^{-1} \log(b-a)^{-1} dx = \log(b-a)$
  - Note that  $h(X) < 0$  if  $(b-a) < 1$
- **Gaussian Distribution:**  $X \sim N(\mu, \sigma^2)$ 
  - $f(x) = (2\pi\sigma^2)^{-1/2} \exp(-1/2(x-\mu)^2 \sigma^{-2})$
  - $h(X) = -(\log e) \int_{-\infty}^{\infty} f(x) \ln f(x) dx$ 

$$= -(\log e) \int_{-\infty}^{\infty} f(x) \left( -1/2 \ln(2\pi\sigma^2) - 1/2(x-\mu)^2 \sigma^{-2} \right)$$

$$= 1/2(\log e) \left( \ln(2\pi\sigma^2) + \sigma^{-2} E((x-\mu)^2) \right)$$

$$= 1/2(\log e) \left( \ln(2\pi\sigma^2) + 1 \right) = 1/2 \log(2\pi e \sigma^2) \cong \log(4.1\sigma) \text{ bits}$$

# Multivariate Gaussian

---

Given mean,  $\mathbf{m}$ , and symmetric +ve definite covariance matrix  $\mathbf{K}$ ,

$$X_{1:n} \sim \mathbf{N}(\mathbf{m}, \mathbf{K}) \Leftrightarrow f(\mathbf{x}) = |2\pi\mathbf{K}|^{-1/2} \exp\left(-\frac{1}{2}(\mathbf{x} - \mathbf{m})^T \mathbf{K}^{-1}(\mathbf{x} - \mathbf{m})\right)$$

$$\begin{aligned} h(f) &= -(\log e) \int f(\mathbf{x}) \times \left( -\frac{1}{2}(\mathbf{x} - \mathbf{m})^T \mathbf{K}^{-1}(\mathbf{x} - \mathbf{m}) - \frac{1}{2} \ln |2\pi\mathbf{K}| \right) d\mathbf{x} \\ &= \frac{1}{2} \log(e) \times \left( \ln |2\pi\mathbf{K}| + E\left((\mathbf{x} - \mathbf{m})^T \mathbf{K}^{-1}(\mathbf{x} - \mathbf{m})\right) \right) \\ &= \frac{1}{2} \log(e) \times \left( \ln |2\pi\mathbf{K}| + E \operatorname{tr}\left((\mathbf{x} - \mathbf{m})(\mathbf{x} - \mathbf{m})^T \mathbf{K}^{-1}\right) \right) \\ &= \frac{1}{2} \log(e) \times \left( \ln |2\pi\mathbf{K}| + \operatorname{tr}\left(E(\mathbf{x} - \mathbf{m})(\mathbf{x} - \mathbf{m})^T \mathbf{K}^{-1}\right) \right) \\ &= \frac{1}{2} \log(e) \times \left( \ln |2\pi\mathbf{K}| + \operatorname{tr}(\mathbf{K}\mathbf{K}^{-1}) \right) = \frac{1}{2} \log(e) \times \left( \ln |2\pi\mathbf{K}| + n \right) \\ &= \frac{1}{2} \log(e^n) + \frac{1}{2} \log(|2\pi\mathbf{K}|) \\ &= \frac{1}{2} \log(|2\pi e\mathbf{K}|) \quad \text{bits} \end{aligned}$$

# Other Differential Quantities

---

## Joint Differential Entropy

$$h(X, Y) = - \iint_{x,y} f_{X,Y}(x, y) \log f_{X,Y}(x, y) dx dy = E - \log f_{X,Y}(x, y)$$

## Conditional Differential Entropy

$$h(X | Y) = - \iint_{x,y} f_{X,Y}(x, y) \log f_{X,Y}(x | y) dx dy = h(X, Y) - h(Y)$$

## Mutual Information

$$I(X; Y) = \iint_{x,y} f_{X,Y}(x, y) \log \frac{f_{X,Y}(x, y)}{f_X(x) f_Y(y)} dx dy = h(X) + h(Y) - h(X, Y)$$

## Relative Differential Entropy of two pdf's:

$$\begin{aligned} D(f \parallel g) &= \int f(x) \log \frac{f(x)}{g(x)} dx \\ &= -h_f(X) - E_f \log g(X) \end{aligned}$$

(a) must have  $f(x)=0 \Rightarrow g(x)=0$

(b) continuity  $\Rightarrow 0 \log(0/0) = 0$

# Differential Entropy Properties

---

Chain Rules  $h(x, y) = h(x) + h(y | x) = h(y) + h(x | y)$   
 $I(x, y; z) = I(x; z) + I(y; z | x)$

Information Inequality:  $D(f || g) \geq 0$

**Proof:** Define  $S = \{\mathbf{x} : f(\mathbf{x}) > 0\}$

$$-D(f || g) = \int_{\mathbf{x} \in S} f(\mathbf{x}) \log \frac{g(\mathbf{x})}{f(\mathbf{x})} d\mathbf{x} = E \left( \log \frac{g(\mathbf{x})}{f(\mathbf{x})} \right)$$

$$\leq \log \left( E \frac{g(\mathbf{x})}{f(\mathbf{x})} \right) = \log \left( \int_S f(\mathbf{x}) \frac{g(\mathbf{x})}{f(\mathbf{x})} d\mathbf{x} \right)$$

Jensen + log() is concave

$$= \log \left( \int_S g(\mathbf{x}) d\mathbf{x} \right) \leq \log 1 = 0$$

all the same as for  $H()$

# Information Inequality Corollaries

---

Mutual Information  $\geq 0$

$$I(X; Y) = D(f_{X,Y} \parallel f_X f_Y) \geq 0$$

Conditioning reduces Entropy

$$h(X) - h(X | Y) = I(X; Y) \geq 0$$

Independence Bound

$$h(X_{1:n}) = \sum_{i=1}^n h(X_i | X_{1:i-1}) \leq \sum_{i=1}^n h(X_i)$$

all the same as for  $H()$

# Change of Variable

---

Change Variable:  $y = g(x)$

$$\text{from earlier} \quad f_y(y) = f_x(g^{-1}(y)) \left| \frac{dg^{-1}(y)}{dy} \right|$$

$$h(y) = -E \log(f_y(y)) = -E \log(f_x(g^{-1}(y))) - E \log \left| \frac{dx}{dy} \right|$$

$$= -E \log(f_x(x)) - E \log \left| \frac{dx}{dy} \right| = h(x) - E \log \left| \frac{dx}{dy} \right|$$

Examples:

- Translation:  $y = x + a \Rightarrow dy/dx = 1 \Rightarrow h(y) = h(x)$
- Scaling:  $y = cx \Rightarrow dy/dx = c \Rightarrow h(y) = h(x) - \log|c^{-1}|$
- Vector version:  $y_{1:n} = \mathbf{A}x_{1:n} \Rightarrow h(\mathbf{y}) = h(\mathbf{x}) + \log|\det(\mathbf{A})|$

not the same as for  $H()$

# Concavity & Convexity

- Differential Entropy:
  - $h(x)$  is a **concave** function of  $f_x(x) \Rightarrow \exists$  a maximum
- Mutual Information:
  - $I(x; y)$  is a **concave** function of  $f_x(x)$  for fixed  $f_{y|x}(y)$
  - $I(x; y)$  is a **convex** function of  $f_{y|x}(y)$  for fixed  $f_x(x)$

## Proofs:

Exactly the same as for the discrete case:  $\mathbf{p}_z = [1-\lambda, \lambda]^T$

$$H(x) \geq H(x|z)$$

$$I(x; y) \geq I(x; y|z)$$

$$I(x; y) \leq I(x; y|z)$$

# Uniform Distribution Entropy

---

What distribution over the finite range  $(a,b)$  maximizes the entropy ?

**Answer:** A uniform distribution  $u(x)=(b-a)^{-1}$

**Proof:**

Suppose  $f(x)$  is a distribution for  $x \in (a,b)$

$$\begin{aligned} 0 \leq D(f \parallel u) &= -h_f(x) - E_f \log u(x) \\ &= -h_f(x) + \log(b-a) \end{aligned}$$

$$\Rightarrow h_f(x) \leq \log(b-a)$$

# Maximum Entropy Distribution

---

What zero-mean distribution maximizes the entropy on  $(-\infty, \infty)^n$  for a given covariance matrix  $\mathbf{K}$  ?

**Answer: A multivariate Gaussian**  $\phi(\mathbf{x}) = |2\pi\mathbf{K}|^{-1/2} \exp(-1/2\mathbf{x}^T\mathbf{K}^{-1}\mathbf{x})$

**Proof:**  $0 \leq D(f \parallel \phi) = -h_f(\mathbf{x}) - E_f \log \phi(\mathbf{x})$

$$\Rightarrow h_f(\mathbf{x}) \leq -(\log e)E_f \left( -1/2 \ln(|2\pi\mathbf{K}|) - 1/2\mathbf{x}^T\mathbf{K}^{-1}\mathbf{x} \right)$$

$$= 1/2(\log e) \left( \ln(|2\pi\mathbf{K}|) + \text{tr}(E_f \mathbf{x}\mathbf{x}^T \mathbf{K}^{-1}) \right)$$

$$= 1/2(\log e) \left( \ln(|2\pi\mathbf{K}|) + \text{tr}(\mathbf{I}) \right)$$

$$E_f \mathbf{x}\mathbf{x}^T = \mathbf{K}$$

$$= 1/2 \log(|2\pi e\mathbf{K}|) = h_\phi(\mathbf{x})$$

$$\text{tr}(\mathbf{I}) = n = \ln(e^n)$$

Since translation doesn't affect  $h(X)$ ,  
we can assume zero-mean w.l.o.g.

# Lecture 14

- Discrete-time Gaussian Channel Capacity
  - Sphere packing
- Continuous Typical Set and AEP
- Gaussian Channel Coding Theorem
- Bandlimited Gaussian Channel
  - Shannon Capacity
  - Channel Codes

# Capacity of Gaussian Channel

Discrete-time channel:  $y_i = x_i + z_i$

- Zero-mean Gaussian i.i.d.  $z_i \sim N(0, N)$
- Average power constraint  $n^{-1} \sum_{i=1}^n x_i^2 \leq P$

$$E y^2 = E(x + z)^2 = E x^2 + 2E(x)E(z) + E z^2 \leq P + N$$

$X, Z$  indep and  $EZ=0$

## Information Capacity

- Define **information capacity**:  $C = \max_{E x^2 \leq P} I(x; y)$

$$I(x; y) = h(y) - h(y | x) = h(y) - h(x + z | x)$$

$$\stackrel{(a)}{=} h(y) - h(z | x) = h(y) - h(z)$$

(a) Translation independence

$$\leq \frac{1}{2} \log 2\pi e(P + N) - \frac{1}{2} \log 2\pi e N$$

Gaussian Limit with equality when  $x \sim N(0, P)$

$$= \frac{1}{2} \log(1 + P N^{-1}) = \frac{1}{6} \left[ \frac{P+N}{N} \right]_{\text{dB}}$$

The optimal input is Gaussian & the worst noise is Gaussian

# Gaussian Channel Code Rate

- An  $(M, n)$  code for a Gaussian Channel with power constraint is
  - A set of  $M$  codewords  $\mathbf{x}(w) \in \mathcal{X}^n$  for  $w=1:M$  with  $\mathbf{x}(w)^T \mathbf{x}(w) \leq nP \quad \forall w$
  - A deterministic decoder  $g(\mathbf{y}) \in 0:M$  where 0 denotes failure
  - Errors: codeword:  $\lambda_i$        $\max_i: \lambda^{(n)}$       average:  $P_e^{(n)}$
- Rate  $R$  is **achievable** if  $\exists$  seq of  $(2^{nR}, n)$  codes with  $\lambda^{(n)} \xrightarrow{n \rightarrow \infty} 0$
- **Theorem:**  $R$  achievable iff  $R < C = \frac{1}{2} \log(1 + PN^{-1})$  ♦

♦ = proved on next pages

# Sphere Packing

- Each transmitted  $\mathbf{x}_i$  is received as a probabilistic cloud  $\mathbf{y}_i$ 
  - cloud 'radius' =  $\sqrt{\text{Var}(\mathbf{y} | \mathbf{x})} = \sqrt{nN}$
- Energy of  $\mathbf{y}_i$  constrained to  $n(P+N)$  so clouds must fit into a hypersphere of radius  $\sqrt{n(P+N)}$
- Volume of hypersphere  $\propto r^n$
- Max number of non-overlapping clouds:

$$\frac{(nP + nN)^{\frac{1}{2}n}}{(nN)^{\frac{1}{2}n}} = 2^{\frac{1}{2}n \log(1 + PN^{-1})}$$

- Max rate is  $\frac{1}{2} \log(1 + PN^{-1})$

# Continuous AEP

**Typical Set:** Continuous distribution, discrete time i.i.d.

For any  $\varepsilon > 0$  and any  $n$ , the **typical set** with respect to  $f(\mathbf{x})$  is

$$T_{\varepsilon}^{(n)} = \left\{ \mathbf{x} \in S^n : \left| -n^{-1} \log f(\mathbf{x}) - h(X) \right| \leq \varepsilon \right\}$$

where  $S$  is the **support** of  $f \Leftrightarrow \{\mathbf{x} : f(\mathbf{x}) > 0\}$

$$f(\mathbf{x}) = \prod_{i=1}^n f(x_i) \text{ since } x_i \text{ are independent}$$

$$h(X) = E - \log f(X) = -n^{-1} E \log f(\mathbf{x})$$

## Typical Set Properties

1.  $p(\mathbf{x} \in T_{\varepsilon}^{(n)}) > 1 - \varepsilon$  for  $n > N_{\varepsilon}$
2.  $(1 - \varepsilon) 2^{n(h(X) - \varepsilon)} \leq \text{Vol}(T_{\varepsilon}^{(n)}) \leq 2^{n(h(X) + \varepsilon)}$

$$\text{where } \text{Vol}(A) = \int_{\mathbf{x} \in A} d\mathbf{x}$$

Proof: WLLN

Proof: Integrate  
max/min prob

# Continuous AEP Proof

---

**Proof 1:** By weak law of large numbers

$$-n^{-1} \log f(x_{1:n}) = -n^{-1} \sum_{i=1}^n \log f(x_i) \xrightarrow{\text{prob}} E - \log f(X) = h(X)$$

Reminder:  $x_n \xrightarrow{\text{prob}} y \Rightarrow \forall \varepsilon > 0, \exists N_\varepsilon$  such that  $\forall n > N_\varepsilon, P(|x_n - y| > \varepsilon) < \varepsilon$

**Proof 2a:**

$$1 - \varepsilon \leq \int_{T_\varepsilon^{(n)}} f(\mathbf{x}) d\mathbf{x} \quad \text{for } n > N_\varepsilon$$

Property 1

$$\leq 2^{-n(h(X) - \varepsilon)} \int_{T_\varepsilon^{(n)}} d\mathbf{x} = 2^{-n(h(X) - \varepsilon)} \text{Vol}(T_\varepsilon^{(n)})$$

max  $f(x)$  within  $T$

**Proof 2b:**

$$1 = \int_{S^n} f(\mathbf{x}) d\mathbf{x} \geq \int_{T_\varepsilon^{(n)}} f(\mathbf{x}) d\mathbf{x}$$

$$\geq 2^{-n(h(X) + \varepsilon)} \int_{T_\varepsilon^{(n)}} d\mathbf{x} = 2^{-n(h(X) + \varepsilon)} \text{Vol}(T_\varepsilon^{(n)})$$

min  $f(x)$  within  $T$

# Jointly Typical Set

**Jointly Typical:**  $x_i, y_i$  i.i.d from  $\mathfrak{R}^2$  with  $f_{X,Y}(x_i, y_i)$

$$J_{\varepsilon}^{(n)} = \left\{ \mathbf{x}, \mathbf{y} \in \mathfrak{R}^{2n} : \begin{aligned} & \left| -n^{-1} \log f_X(\mathbf{x}) - h(X) \right| < \varepsilon, \\ & \left| -n^{-1} \log f_Y(\mathbf{y}) - h(Y) \right| < \varepsilon, \\ & \left| -n^{-1} \log f_{X,Y}(\mathbf{x}, \mathbf{y}) - h(X, Y) \right| < \varepsilon \end{aligned} \right\}$$

**Properties:**

1. Indiv p.d.:  $\mathbf{x}, \mathbf{y} \in J_{\varepsilon}^{(n)} \Rightarrow \log f_{X,Y}(\mathbf{x}, \mathbf{y}) = -nh(X, Y) \pm n\varepsilon$
2. Total Prob:  $p(\mathbf{x}, \mathbf{y} \in J_{\varepsilon}^{(n)}) > 1 - \varepsilon$  for  $n > N_{\varepsilon}$
3. Size:  $(1 - \varepsilon)2^{n(h(X,Y) - \varepsilon)} \stackrel{n > N_{\varepsilon}}{\leq} \text{Vol}(J_{\varepsilon}^{(n)}) \leq 2^{n(h(X,Y) + \varepsilon)}$
4. Indep  $\mathbf{x}', \mathbf{y}'$ :  $(1 - \varepsilon)2^{-n(I(X,Y) + 3\varepsilon)} \stackrel{n > N_{\varepsilon}}{\leq} p(\mathbf{x}', \mathbf{y}' \in J_{\varepsilon}^{(n)}) \leq 2^{-n(I(X,Y) - 3\varepsilon)}$

Proof of 4.: Integrate max/min  $f(\mathbf{x}', \mathbf{y}') = f(\mathbf{x}')f(\mathbf{y}')$ , then use known bounds on  $\text{Vol}(J)$

# Gaussian Channel Coding Theorem

---

$R$  is achievable iff  $R < C = \frac{1}{2} \log(1 + PN^{-1})$

Proof ( $\Leftarrow$ ):

Choose  $\varepsilon > 0$

Random codebook:  $\mathbf{x}_w \in \mathbb{R}^n$  for  $w = 1:2^{nR}$  where  $x_w$  are i.i.d.  $\sim N(0, P - \varepsilon)$

Use Joint typicality decoding

Errors: 1. Power too big  $p(\mathbf{x}^T \mathbf{x} > nP) \rightarrow 0 \Rightarrow \leq \varepsilon$  for  $n > M_\varepsilon$

2.  $\mathbf{y}$  not J.T. with  $\mathbf{x}$   $p(\mathbf{x}, \mathbf{y} \notin J_\varepsilon^{(n)}) < \varepsilon$  for  $n > N_\varepsilon$

3. another  $\mathbf{x}$  J.T. with  $\mathbf{y}$   $\sum_{j=2}^{2^{nR}} p(\mathbf{x}_j, \mathbf{y}_i \in J_\varepsilon^{(n)}) \leq (2^{nR} - 1) \times 2^{-n(I(X;Y) - 3\varepsilon)}$

Total Err  $P_\varepsilon^{(n)} \leq \varepsilon + \varepsilon + 2^{-n(I(X;Y) - R - 3\varepsilon)} \leq 3\varepsilon$  for large  $n$  if  $R < I(X;Y) - 3\varepsilon$

Expurgation: Remove half of codebook\*:  $\lambda^{(n)} < 6\varepsilon$  now max error

We have constructed a code achieving rate  $R - n^{-1}$

\*: Worst codebook half includes  $\mathbf{x}_i$ :  $\mathbf{x}_i^T \mathbf{x}_i > nP \Rightarrow \lambda_i = 1$

# Gaussian Channel Coding Theorem

Proof ( $\Rightarrow$ ): Assume  $P_\varepsilon^{(n)} \rightarrow 0$  and  $n^{-1} \mathbf{x}^T \mathbf{x} < P$  for each  $\mathbf{x}(w)$

$$nR = H(W) = I(W; \mathbf{y}_{1:n}) + H(W | \mathbf{y}_{1:n})$$

$$\leq I(\mathbf{x}_{1:n}; \mathbf{y}_{1:n}) + H(W | \mathbf{y}_{1:n})$$

Data Proc Inequal

$$= h(\mathbf{y}_{1:n}) - h(\mathbf{y}_{1:n} | \mathbf{x}_{1:n}) + H(W | \mathbf{y}_{1:n})$$

$$\leq \sum_{i=1}^n h(y_i) - h(\mathbf{z}_{1:n}) + H(W | \mathbf{y}_{1:n})$$

Indep Bound + Translation

$$\leq \sum_{i=1}^n I(x_i; y_i) + 1 + nRP_\varepsilon^{(n)}$$

Z i.i.d + Fano,  $|\mathbf{W}| = 2^{nR}$

$$\leq \sum_{i=1}^n \frac{1}{2} \log(1 + PN^{-1}) + 1 + nRP_\varepsilon^{(n)}$$

max Information Capacity

$$R \leq \frac{1}{2} \log(1 + PN^{-1}) + n^{-1} + RP_\varepsilon^{(n)} \rightarrow \frac{1}{2} \log(1 + PN^{-1})$$

# Bandlimited Channel

---

- Channel **bandlimited** to  $f \in (-W, W)$  and signal duration  $T$
- **Nyquist**: Signal is completely defined by  $2WT$  samples
- Can represent as a  $n=2WT$ -dimensional vector space with **prolate spheroidal functions** as an orthonormal basis
  - white noise with double-sided p.s.d.  $\frac{1}{2}N_0$  becomes i.i.d gaussian  $N(0, \frac{1}{2}N_0)$  added to each coefficient
  - Signal power constraint =  $P \Rightarrow$  Signal energy  $\leq PT$ 
    - Energy constraint per coefficient:  $n^{-1} \mathbf{x}^T \mathbf{x} < PT/2WT = \frac{1}{2}W^{-1}P$
- **Capacity**:
 
$$C = \frac{1}{2} \log \left( 1 + \frac{1}{2}W^{-1}P(N_0)^{-1} \right) \times 2W$$

$$= W \log \left( 1 + N_0^{-1}W^{-1}P \right) \text{ bits/second}$$

Compare discrete time version:  $\frac{1}{2} \log(1 + PN^{-1})$  bits per channel use

# Shannon Capacity

Bandwidth =  $W$  Hz, Signal variance =  $\frac{1}{2}W^{-1}P$ , Noise variance =  $\frac{1}{2}N_0$

Signal Power =  $P$ , Noise power =  $N_0W$ , Min bit energy =  $E_b = PC^{-1}$

Capacity =  $C = W \log(1 + PN_0^{-1}W^{-1})$  bits per second

**Define:**  $W_0 = PN_0^{-1} \Rightarrow C/W_0 = (W/W_0) \log(1 + (W/W_0)^{-1}) \xrightarrow{W \rightarrow \infty} \log e$   
 $\Rightarrow C^{-1}W_0 = E_b N_0^{-1} \xrightarrow{W \rightarrow \infty} \ln 2 = -1.6 \text{ dB}$

- For fixed power, high bandwidth is better – Ultra wideband

# Practical Channel Codes

---

## Code Classification:

- **Very good**: arbitrarily small error up to the capacity
- **Good**: arbitrarily small error up to less than capacity
- **Bad**: arbitrarily small error only at zero rate (or never)

## Coding Theorem: Nearly all codes are very good

- but nearly all codes need encode/decode computation  $\propto 2^n$

## Practical Good Codes:

- **Practical**: Computation & memory  $\propto n^k$  for some  $k$
- **Convolution Codes**: convolve bit stream with a filter
  - Concatenation, Interleaving, turbo codes (1993)
- **Block codes**: encode a block at a time
  - Hamming, BCH, Reed-Solomon, LD parity check (1995)

# Channel Code Performance

- **Power Limited**
  - High bandwidth
  - Spacecraft, Pagers
  - Use QPSK/4-QAM
  - Block/Convolution Codes
- **Bandwidth Limited**
  - Modems, DVB, Mobile phones
  - 16-QAM to 256-QAM
  - Convolution Codes
- **Value of 1 dB for space**
  - Better range, lifetime, weight, bit rate
  - \$80 M (1999)

# Lecture 15

---

- Parallel Gaussian Channels
  - Waterfilling
- Gaussian Channel with Feedback

# Parallel Gaussian Channels

- $n$  gaussian channels (or one channel  $n$  times)
  - e.g. digital audio, digital TV, Broadband ADSL
- Noise is independent  $z_i \sim N(0, N_i)$
- Average Power constraint  $E\mathbf{x}^T\mathbf{x} \leq P$
- Information Capacity:  $C = \max_{f(\mathbf{x}): E_f \mathbf{x}^T \mathbf{x} \leq P} I(\mathbf{x}; \mathbf{y})$
- $R < C \Leftrightarrow R$  achievable
  - proof as before
- What is the optimal  $f(\mathbf{x})$  ?

# Parallel Gaussian: Max Capacity

---

Need to find  $f(\mathbf{x})$ :  $C = \max_{f(\mathbf{x}): E_f \mathbf{x}^T \mathbf{x} \leq P} I(\mathbf{x}; \mathbf{y})$

$$I(\mathbf{x}; \mathbf{y}) = h(\mathbf{y}) - h(\mathbf{y} | \mathbf{x}) = h(\mathbf{y}) - h(\mathbf{z} | \mathbf{x})$$

Translation invariance

$$= h(\mathbf{y}) - h(\mathbf{z}) = h(\mathbf{y}) - \sum_{i=1}^n h(z_i)$$

$\mathbf{x}, \mathbf{z}$  indep;  $Z_i$  indep

$$\stackrel{(a)}{\leq} \sum_{i=1}^n (h(y_i) - h(z_i)) \stackrel{(b)}{\leq} \sum_{i=1}^n \frac{1}{2} \log(1 + P_i N_i^{-1})$$

(a) indep bound;  
(b) capacity limit

Equality when: (a)  $y_i$  indep  $\Rightarrow x_i$  indep; (b)  $x_i \sim N(0, P_i)$

We need to find the  $P_i$  that maximise  $\sum_{i=1}^n \frac{1}{2} \log(1 + P_i N_i^{-1})$

# Parallel Gaussian: Optimal Powers

We need to find the  $P_i$  that maximise  $\log(e) \sum_{i=1}^n \frac{1}{2} \ln(1 + P_i N_i^{-1})$

- subject to power constraint  $\sum_{i=1}^n P_i = P$
- use Lagrange multiplier

$$J = \sum_{i=1}^n \frac{1}{2} \ln(1 + P_i N_i^{-1}) - \lambda \sum_{i=1}^n P_i$$

$$\frac{\partial J}{\partial P_i} = \frac{1}{2} (P_i + N_i)^{-1} - \lambda = 0 \Rightarrow P_i + N_i = \frac{1}{2} \lambda^{-1}$$

$$\text{Also } \sum_{i=1}^n P_i = P \Rightarrow \lambda = \frac{1}{2} n \left( P + \sum_{i=1}^n N_i \right)^{-1}$$

**Water Filling:** put most power into least noisy channels to make equal power + noise in each channel

# Very Noisy Channels

- Must have  $P_j \geq 0 \ \forall i$
- If  $\frac{1}{2}\lambda^{-1} < N_j$  then set  $P_j=0$  and recalculate  $\lambda$

Kuhn Tucker Conditions:

(not examinable)

- Max  $f(\mathbf{x})$  subject to  $\mathbf{Ax} + \mathbf{b} = \mathbf{0}$  and  $g_i(\mathbf{x}) \geq 0$  for  $i \in 1:M$  with  $f, g_i$  concave
- set  $J(\mathbf{x}) = f(\mathbf{x}) - \sum_{i=1}^M \mu_i g_i(\mathbf{x}) - \lambda^T \mathbf{Ax}$
- Solution  $\mathbf{x}_0, \lambda, \mu_i$  iff

$$\nabla J(\mathbf{x}_0) = 0, \quad \mathbf{Ax} + \mathbf{b} = \mathbf{0}, \quad g_i(\mathbf{x}_0) \geq 0, \quad \mu_i \geq 0, \quad \mu_i g_i(\mathbf{x}_0) = 0$$

# Correlated Noise

- Suppose  $\mathbf{y} = \mathbf{x} + \mathbf{z}$  where  $E \mathbf{z}\mathbf{z}^T = \mathbf{K}_z$  and  $E \mathbf{x}\mathbf{x}^T = \mathbf{K}_x$
- We want to find  $\mathbf{K}_x$  to maximize capacity subject to power constraint:  $E \sum_{i=1}^n x_i^2 \leq nP \Leftrightarrow \text{tr}(\mathbf{K}_x) \leq nP$ 
  - Find noise eigenvectors:  $\mathbf{K}_z = \mathbf{Q}\mathbf{D}\mathbf{Q}^T$  with  $\mathbf{Q}\mathbf{Q}^T = \mathbf{I}$
  - Now  $\mathbf{Q}^T\mathbf{y} = \mathbf{Q}^T\mathbf{x} + \mathbf{Q}^T\mathbf{z} = \mathbf{Q}^T\mathbf{x} + \mathbf{w}$   
 where  $E \mathbf{w}\mathbf{w}^T = E \mathbf{Q}^T\mathbf{z}\mathbf{z}^T\mathbf{Q} = E \mathbf{Q}^T\mathbf{K}_z\mathbf{Q} = \mathbf{D}$  is diagonal
    - $\Rightarrow W_i$  are now independent
  - Power constraint is unchanged  $\text{tr}(\mathbf{Q}^T\mathbf{K}_x\mathbf{Q}) = \text{tr}(\mathbf{K}_x\mathbf{Q}\mathbf{Q}^T) = \text{tr}(\mathbf{K}_x)$
  - Choose  $\mathbf{Q}^T\mathbf{K}_x\mathbf{Q} = L\mathbf{I} - \mathbf{D}$  where  $L = P + n^{-1} \text{tr}(\mathbf{D})$   
 $\Rightarrow \mathbf{K}_x = \mathbf{Q}(L\mathbf{I} - \mathbf{D})\mathbf{Q}^T$

# Power Spectrum Water Filling

- If  $\mathbf{z}$  is from a stationary process then  $\text{diag}(\mathbf{D}) \xrightarrow{n \rightarrow \infty}$  power spectrum
  - To achieve capacity use waterfilling on noise power spectrum

$$P = \int_{-W}^W \max(L - N(f), 0) df$$

$$C = \int_{-W}^W \frac{1}{2} \log \left( 1 + \frac{\max(L - N(f), 0)}{N(f)} \right) df$$

# Gaussian Channel + Feedback

Does Feedback add capacity ?

- White noise – No
- Coloured noise – Not much

$$I(w; \mathbf{y}) = h(\mathbf{y}) - h(\mathbf{y} | w) = h(\mathbf{y}) - \sum_{i=1}^n h(y_i | w, y_{1:i-1}) \quad \text{Chain rule}$$

$$= h(\mathbf{y}) - \sum_{i=1}^n h(y_i | w, y_{1:i-1}, x_{1:i}, z_{1:i-1})$$

$$x_i = x_i(w, y_{1:i-1}), \mathbf{z} = \mathbf{y} - \mathbf{x}$$

$$= h(\mathbf{y}) - \sum_{i=1}^n h(z_i | w, y_{1:i-1}, x_{1:i}, z_{1:i-1})$$

$\mathbf{z} = \mathbf{y} - \mathbf{x}$  and translation invariance

$$= h(\mathbf{y}) - \sum_{i=1}^n h(z_i | z_{1:i-1})$$

$z_i$  depends only on  $z_{1:i-1}$

$$= h(\mathbf{y}) - h(\mathbf{z})$$

Chain rule,  $h(\mathbf{z}) = \frac{1}{2} \log(|2\pi e \mathbf{K}_z|)$  bits

$$= \frac{1}{2} \log \frac{|\mathbf{K}_y|}{|\mathbf{K}_z|}$$

$\Rightarrow$  maximize  $I(w; \mathbf{y})$  by maximizing  $h(\mathbf{y}) \Rightarrow \mathbf{y}$  gaussian

$\Rightarrow$  we can take  $\mathbf{z}$  and  $\mathbf{x} = \mathbf{y} - \mathbf{z}$  jointly gaussian

# Gaussian Feedback Coder

$\mathbf{x}$  and  $\mathbf{z}$  jointly gaussian  $\Rightarrow$

$$\mathbf{x} = \mathbf{B}\mathbf{z} + \mathbf{v}(W)$$

where  $\mathbf{v}$  is indep of  $\mathbf{z}$  and

$\mathbf{B}$  is strictly lower triangular since  $x_i$  indep of  $z_j$  for  $j > i$ .

$$\mathbf{y} = \mathbf{x} + \mathbf{z} = (\mathbf{B} + \mathbf{I})\mathbf{z} + \mathbf{v}$$

$$\mathbf{K}_y = E\mathbf{y}\mathbf{y}^T = E\left((\mathbf{B} + \mathbf{I})\mathbf{z}\mathbf{z}^T(\mathbf{B} + \mathbf{I})^T + \mathbf{v}\mathbf{v}^T\right) = (\mathbf{B} + \mathbf{I})\mathbf{K}_z(\mathbf{B} + \mathbf{I})^T + \mathbf{K}_v$$

$$\mathbf{K}_x = E\mathbf{x}\mathbf{x}^T = E\left(\mathbf{B}\mathbf{z}\mathbf{z}^T\mathbf{B}^T + \mathbf{v}\mathbf{v}^T\right) = \mathbf{B}\mathbf{K}_z\mathbf{B}^T + \mathbf{K}_v$$

Capacity: 
$$C_{n,FB} = \max_{\mathbf{K}_v, \mathbf{B}} \frac{1}{2} n^{-1} \frac{|\mathbf{K}_y|}{|\mathbf{K}_z|} = \max_{\mathbf{K}_v, \mathbf{B}} \frac{1}{2} n^{-1} \log \frac{|(\mathbf{B} + \mathbf{I})\mathbf{K}_z(\mathbf{B} + \mathbf{I})^T + \mathbf{K}_v|}{|\mathbf{K}_z|}$$

subject to 
$$\mathbf{K}_x = \text{tr}(\mathbf{B}\mathbf{K}_z\mathbf{B}^T + \mathbf{K}_v) \leq nP$$

hard to solve ☹

# Gaussian Feedback: Toy Example

$$n = 2, \quad P = 2, \quad \mathbf{K}_z = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, \quad \mathbf{B} = \begin{pmatrix} 0 & 0 \\ b & 0 \end{pmatrix}$$

$$\mathbf{x} = \mathbf{B}\mathbf{z} + \mathbf{v}$$

Goal: Maximize (w.r.t.  $\mathbf{K}_v$  and  $b$ )

$$\det(\mathbf{K}_y) = \det((\mathbf{B} + \mathbf{I})\mathbf{K}_z(\mathbf{B} + \mathbf{I})^T + \mathbf{K}_v)$$

Subject to:

$\mathbf{K}_v$  must be positive definite

$$\text{Power constraint : } \text{tr}(\mathbf{B}\mathbf{K}_z\mathbf{B}^T + \mathbf{K}_v) \leq 4$$

Solution (via numerically search):

$$b=0: \quad \det(\mathbf{K}_y)=16 \quad C=0.604 \text{ bits}$$

$$b=0.69: \quad \det(\mathbf{K}_y)=20.7 \quad C=0.697 \text{ bits}$$

Feedback increases  $C$  by 16%

# Max Benefit of Feedback: Lemmas

---

Lemma 1:  $\mathbf{K}_{\mathbf{x}+\mathbf{z}} + \mathbf{K}_{\mathbf{x}-\mathbf{z}} = 2(\mathbf{K}_{\mathbf{x}} + \mathbf{K}_{\mathbf{z}})$

$$\begin{aligned}\mathbf{K}_{\mathbf{x}+\mathbf{z}} + \mathbf{K}_{\mathbf{x}-\mathbf{z}} &= E(\mathbf{x} + \mathbf{z})(\mathbf{x} + \mathbf{z})^T + E(\mathbf{x} - \mathbf{z})(\mathbf{x} - \mathbf{z})^T \\ &= E(\mathbf{x}\mathbf{x}^T + \mathbf{x}\mathbf{z}^T + \mathbf{z}\mathbf{x}^T + \mathbf{z}\mathbf{z}^T + \mathbf{x}\mathbf{x}^T - \mathbf{x}\mathbf{z}^T - \mathbf{z}\mathbf{x}^T + \mathbf{z}\mathbf{z}^T) \\ &= E(2\mathbf{x}\mathbf{x}^T + 2\mathbf{z}\mathbf{z}^T) = 2(\mathbf{K}_{\mathbf{x}} + \mathbf{K}_{\mathbf{z}})\end{aligned}$$

Lemma 2: If  $\mathbf{F}, \mathbf{G}$  are +ve definite then  $\det(\mathbf{F} + \mathbf{G}) \geq \det(\mathbf{F})$

Consider two indep random vectors  $\mathbf{f} \sim N(0, \mathbf{F})$ ,  $\mathbf{g} \sim N(0, \mathbf{G})$

$$\begin{aligned}\frac{1}{2} \log \left( (2\pi e)^n \det(\mathbf{F} + \mathbf{G}) \right) &= h(\mathbf{f} + \mathbf{g}) \\ &\geq h(\mathbf{f} + \mathbf{g} | \mathbf{g}) = h(\mathbf{f} | \mathbf{g}) && \text{Conditioning reduces } h() \\ &= h(\mathbf{f}) = \frac{1}{2} \log \left( (2\pi e)^n \det(\mathbf{F}) \right) && \text{Translation invariance} \\ &&& \mathbf{f}, \mathbf{g} \text{ independent}\end{aligned}$$

Hence:  $\det(2(\mathbf{K}_{\mathbf{x}} + \mathbf{K}_{\mathbf{z}})) = \det(\mathbf{K}_{\mathbf{x}+\mathbf{z}} + \mathbf{K}_{\mathbf{x}-\mathbf{z}}) \geq \det(\mathbf{K}_{\mathbf{x}+\mathbf{z}}) = \det(\mathbf{K}_{\mathbf{y}})$

# Maximum Benefit of Feedback

$$C_{n,FB} \leq \max_{\text{tr}(\mathbf{K}_x) \leq nP} \frac{1}{2} n^{-1} \log \frac{\det(\mathbf{K}_y)}{\det(\mathbf{K}_z)}$$

$$\leq \max_{\text{tr}(\mathbf{K}_x) \leq nP} \frac{1}{2} n^{-1} \log \frac{\det(2(\mathbf{K}_x + \mathbf{K}_z))}{\det(\mathbf{K}_z)}$$

$$= \max_{\text{tr}(\mathbf{K}_x) \leq nP} \frac{1}{2} n^{-1} \log \frac{2^n \det(\mathbf{K}_x + \mathbf{K}_z)}{\det(\mathbf{K}_z)}$$

$$= \frac{1}{2} + \max_{\text{tr}(\mathbf{K}_x) \leq nP} \frac{1}{2} n^{-1} \log \frac{\det(\mathbf{K}_x + \mathbf{K}_z)}{\det(\mathbf{K}_z)} = \frac{1}{2} + C_n \text{ bits/transmission}$$

$\mathbf{K}_y = \mathbf{K}_x + \mathbf{K}_z$  if no feedback

no constraint on  $\mathbf{B} \Rightarrow \leq$

Lemmas 1 & 2:

$$\det(2(\mathbf{K}_x + \mathbf{K}_z)) \geq \det(\mathbf{K}_y)$$

$$\det(k\mathbf{A}) = k^n \det(\mathbf{A})$$

Having feedback adds at most  $\frac{1}{2}$  bit per transmission

# Lecture 16

---

- Lossy Coding
- Rate Distortion
  - Bernoulli Source
  - Gaussian Source
- Channel/Source Coding Duality

# Lossy Coding

**Distortion function:**  $d(x, \hat{x}) \geq 0$

– examples: (i)  $d_S(x, \hat{x}) = (x - \hat{x})^2$       (ii)  $d_H(x, \hat{x}) = \begin{cases} 0 & x = \hat{x} \\ 1 & x \neq \hat{x} \end{cases}$

– sequences:  $d(\mathbf{x}, \hat{\mathbf{x}}) \triangleq n^{-1} \sum_{i=1}^n d(x_i, \hat{x}_i)$

**Distortion of Code  $f_n(), g_n()$ :**  $D = E_{\mathbf{x} \in \mathcal{X}^n} d(\mathbf{x}, \hat{\mathbf{x}}) = E d(\mathbf{x}, g(f(\mathbf{x})))$

**Rate distortion pair (R,D) is achievable for source  $\mathbf{X}$  if**

$\exists$  a sequence  $f_n()$  and  $g_n()$  such that  $\lim_{n \rightarrow \infty} E_{\mathbf{x} \in \mathcal{X}^n} d(\mathbf{x}, g_n(f_n(\mathbf{x}))) \leq D$

# Rate Distortion Function

---

Rate Distortion function for  $\{x_i\}$  where  $p(\mathbf{x})$  is known is

$$R(D) = \inf R \text{ such that } (R, D) \text{ is achievable}$$

Theorem:  $R(D) = \min I(X; \hat{X})$  over all  $p(x, \hat{x})$  such that :

(a)  $p(x)$  is correct

(b)  $E_{x, \hat{x}} d(x, \hat{x}) \leq D$

– this expression is the Information Rate Distortion function for  $X$

We will prove this next lecture

If  $D=0$  then we have  $R(D)=I(X; \hat{X})=H(X)$

# $R(D)$ bound for Bernoulli Source

Bernoulli:  $\mathcal{X} = [0,1]$ ,  $\mathbf{p}_X = [1-p, p]$  assume  $p \leq 1/2$

- Hamming Distance:  $d(x, \hat{x}) = x \oplus \hat{x}$
- If  $D \geq p$ ,  $R(D)=0$  since we can set  $g(\cdot) \equiv 0$
- For  $D < p \leq 1/2$ , if  $E d(x, \hat{x}) \leq D$  then

$$\begin{aligned} I(X; \hat{X}) &= H(X) - H(X | \hat{X}) \\ &= H(p) - H(X \oplus \hat{X} | \hat{X}) \\ &\geq H(p) - H(X \oplus \hat{X}) \\ &\geq H(p) - H(D) \end{aligned}$$

Hence  $R(D) \geq H(p) - H(D)$

$\oplus$  is one-to-one

Conditioning reduces entropy

$p(X \oplus \hat{X}) \leq D$  and so for  $D \leq 1/2$

$H(X \oplus \hat{X}) \leq H(D)$  as  $H(p)$  monotonic

# $R(D)$ for Bernoulli source

We know optimum satisfies  $R(D) \geq H(p) - H(D)$

- We show we can find a  $p(\hat{x}, x)$  that attains this.
- Peculiarly, we consider a **channel** with  $\hat{x}$  as the **input** and error probability  $D$

Now choose  $r$  to give  $x$  the correct probabilities:

$$r(1-D) + (1-r)D = p$$

$$\Rightarrow r = (p-D)(1-2D)^{-1}$$

Now  $I(x; \hat{x}) = H(x) - H(x | \hat{x}) = H(p) - H(D)$

and  $p(x \neq \hat{x}) = D$

Hence  $R(D) = H(p) - H(D)$

# $R(D)$ bound for Gaussian Source

---

- Assume  $X \sim N(0, \sigma^2)$  and  $d(x, \hat{x}) = (x - \hat{x})^2$
- Want to minimize  $I(X; \hat{X})$  subject to  $E(X - \hat{X})^2 \leq D$

$$I(X; \hat{X}) = h(X) - h(X | \hat{X})$$

$$= \frac{1}{2} \log 2\pi e \sigma^2 - h(X - \hat{X} | \hat{X})$$

Translation Invariance

$$\geq \frac{1}{2} \log 2\pi e \sigma^2 - h(X - \hat{X})$$

Conditioning reduces entropy

$$\geq \frac{1}{2} \log 2\pi e \sigma^2 - \frac{1}{2} \log (2\pi e \text{Var}(X - \hat{X}))$$

Gauss maximizes entropy  
for given covariance

$$\geq \frac{1}{2} \log 2\pi e \sigma^2 - \frac{1}{2} \log 2\pi e D$$

require  $\text{Var}(X - \hat{X}) \leq E(X - \hat{X})^2 \leq D$

$$I(X; \hat{X}) \geq \max \left( \frac{1}{2} \log \frac{\sigma^2}{D}, 0 \right)$$

$I(X; Y)$  always positive

# $R(D)$ for Gaussian Source

To show that we can find a  $p(\hat{x}, x)$  that achieves the bound, we construct a **test channel** that introduces distortion  $D < \sigma^2$

$$\begin{aligned}
 I(X; \hat{X}) &= h(X) - h(X | \hat{X}) \\
 &= \frac{1}{2} \log 2\pi e \sigma^2 - h(X - \hat{X} | \hat{X}) \\
 &= \frac{1}{2} \log 2\pi e \sigma^2 - h(Z | \hat{X}) \\
 &= \frac{1}{2} \log \frac{\sigma^2}{D}
 \end{aligned}$$

$$\Rightarrow D(R) = \left( \frac{\sigma}{2^R} \right)^2$$

# Lloyd Algorithm

**Problem:** Find optimum quantization levels for Gaussian pdf

- Bin boundaries are midway between quantization levels
- Each quantization level equals the mean value of its own bin

**Lloyd algorithm:** Pick random quantization levels then apply conditions (a) and (b) in turn until convergence.

Solid lines are bin boundaries. Initial levels uniform in  $[-1, +1]$ .

Best mean sq error for 8 levels =  $0.0345\sigma^2$ . Predicted  $D(R) = (\sigma/8)^2 = 0.0156\sigma^2$

# Vector Quantization

To get  $D(R)$ , you have to quantize many values together

- True even if the values are independent

Two gaussian variables: one quadrant only shown

- Independent quantization puts dense levels in low prob areas
- Vector quantization is better (even more so if correlated)

# Multiple Gaussian Variables

---

- Assume  $x_{1:n}$  are independent gaussian sources with different variances. How should we apportion the available total distortion between the sources?
- Assume  $x_i \sim N(0, \sigma_i^2)$  and  $d(\mathbf{x}, \hat{\mathbf{x}}) = n^{-1}(\mathbf{x} - \hat{\mathbf{x}})^T(\mathbf{x} - \hat{\mathbf{x}}) \leq D$

$$I(x_{1:n}; \hat{x}_{1:n}) \geq \sum_{i=1}^n I(x_i; \hat{x}_i)$$

Mut Info Independence Bound  
for independent  $x_i$

$$\geq \sum_{i=1}^n R(D_i) = \sum_{i=1}^n \max\left(\frac{1}{2} \log \frac{\sigma_i^2}{D_i}, 0\right)$$

$R(D)$  for individual  
Gaussian

We must find the  $D_i$  that minimize  $\sum_{i=1}^n \max\left(\frac{1}{2} \log \frac{\sigma_i^2}{D_i}, 0\right)$

# Reverse Waterfilling

$$\text{Minimize } \sum_{i=1}^n \max\left(\frac{1}{2} \log \frac{\sigma_i^2}{D_i}, 0\right) \text{ subject to } \sum_{i=1}^n D_i \leq nD$$

Use a lagrange multiplier:

$$J = \sum_{i=1}^n \frac{1}{2} \log \frac{\sigma_i^2}{D_i} + \lambda \sum_{i=1}^n D_i$$

$$\frac{\partial J}{\partial D_i} = -\frac{1}{2} D_i^{-1} + \lambda = 0 \Rightarrow D_i = \frac{1}{2} \lambda^{-1} = D_0$$

$$\sum_{i=1}^n D_i = nD_0 = nD \Rightarrow D_0 = D$$

Choose  $R_i$  for equal distortion

- If  $\sigma_i^2 < D$  then set  $R_i=0$  and increase  $D_0$  to maintain the average distortion equal to  $D$
- If  $x_i$  are correlated then reverse waterfill the eigenvectors of the correlation matrix

# Channel/Source Coding Duality

- Channel Coding

- Find codes separated enough to give non-overlapping output images.
- Image size = channel noise
- The maximum number (highest rate) is when the images just fill the sphere.

Sphere Packing

- Source Coding

- Find regions that cover the sphere
- Region size = allowed distortion
- The minimum number (lowest rate) is when they just don't overlap

Sphere Covering

# Channel Decoder as Source Coder

- For  $R \cong C = \frac{1}{2} \log \left( 1 + (\sigma^2 - D) D^{-1} \right)$ , we can find a channel encoder/decoder so that  $p(\hat{w} \neq w) < \varepsilon$  and  $E(x_i - y_i)^2 = D$
- Reverse the roles of encoder and decoder. Since  $p(w \neq \hat{w}) < \varepsilon$ , also  $p(\hat{x} \neq y) < \varepsilon$  and  $E(x_i - \hat{x}_i)^2 \cong E(x_i - y_i)^2 = D$

We have encoded  $x$  at rate  $R = \frac{1}{2} \log(\sigma^2 D^{-1})$  with distortion  $D$

# High Dimensional Space

## In $n$ dimensions

- “Vol” of unit hypercube: 1
- “Vol” of unit-diameter hypersphere:

$$V_n = \begin{cases} \pi^{1/2 n - 1/2} (1/2 n - 1/2)! / n! & n \text{ odd} \\ \pi^{1/2 n} 2^{-n} / (1/2 n)! & n \text{ even} \end{cases}$$

- “Area” of unit-diameter hypersphere:

$$A_n = \frac{d}{dr} (2r)^n V_n \Big|_{r=1/2} = 2n V_n$$

- >63% of  $V_n$  is in shell  $(1 - n^{-1})R \leq r \leq R$

$$\text{Proof: } (1 - n^{-1})^n \xrightarrow[n \rightarrow \infty]{} e^{-1} = 0.3679$$

| $n$ | $V_n$   | $A_n$   |
|-----|---------|---------|
| 1   | 1       | 2       |
| 2   | 0.79    | 3.14    |
| 3   | 0.52    | 3.14    |
| 4   | 0.31    | 2.47    |
| 10  | 2.5e-3  | 5e-2    |
| 100 | 1.9e-70 | 3.7e-68 |

Most of  $n$ -dimensional space is in the corners

# Lecture 17

---

- Rate Distortion Theorem

# Review

Rate Distortion function for  $x$  whose  $p_{\mathbf{x}}(\mathbf{x})$  is known is

$$R(D) = \inf R \text{ such that } \exists f_n, g_n \text{ with } \lim_{n \rightarrow \infty} E_{\mathbf{x} \in \mathcal{X}^n} d(\mathbf{x}, \hat{\mathbf{x}}) \leq D$$

Rate Distortion Theorem:

$$R(D) = \min I(x; \hat{x}) \text{ over all } p(\hat{x} | x) \text{ such that } E_{x, \hat{x}} d(x, \hat{x}) \leq D$$

We will prove this theorem for discrete  $X$   
and bounded  $d(x, y) \leq d_{\max}$

$R(D)$  curve depends on your choice of  $d(\cdot)$

# Rate Distortion Bound

---

Suppose we have found an encoder and decoder at rate  $R_0$  with expected distortion  $D$  for independent  $x_i$  (worst case)

We want to prove that  $R_0 \geq R(D) = R(E d(\mathbf{x}; \hat{\mathbf{x}}))$

- We show first that  $R_0 \geq n^{-1} \sum_i I(x_i; \hat{x}_i)$
- We know that  $I(x_i; \hat{x}_i) \geq R(E d(x_i; \hat{x}_i))$  Def<sup>n</sup> of  $R(D)$
- and use convexity to show

$$n^{-1} \sum_i R(E d(x_i; \hat{x}_i)) \geq R(E d(\mathbf{x}; \hat{\mathbf{x}})) = R(D)$$

We prove convexity first and then the rest

# Convexity of $R(D)$

If  $p_1(\hat{x} | x)$  and  $p_2(\hat{x} | x)$  are associated with  $(D_1, R_1)$  and  $(D_2, R_2)$  on the  $R(D)$  curve we define

$$p_\lambda(\hat{x} | x) = \lambda p_1(\hat{x} | x) + (1 - \lambda) p_2(\hat{x} | x)$$

Then

$$E_{p_\lambda} d(x, \hat{x}) = \lambda D_1 + (1 - \lambda) D_2 = D_\lambda$$

$$R(D_\lambda) \leq I_{p_\lambda}(x; \hat{x})$$

$$\leq \lambda I_{p_1}(x; \hat{x}) + (1 - \lambda) I_{p_2}(x; \hat{x})$$

$$= \lambda R(D_1) + (1 - \lambda) R(D_2)$$

$$R(D) = \min_{p(\hat{x}|x)} I(x; \hat{x})$$

$I(x; \hat{x})$  convex w.r.t.  $p(\hat{x} | x)$

$p_1$  and  $p_2$  lie on the  $R(D)$  curve

# Proof that $R \geq R(D)$

---

$$nR_0 \geq H(\hat{X}_{1:n}) = H(\hat{X}_{1:n}) - H(\hat{X}_{1:n} \mid X_{1:n}) \quad \text{Uniform bound; } H(\hat{X} \mid X) = 0$$

$$= I(\hat{X}_{1:n}; X_{1:n}) \quad \text{Definition of } I(;)$$

$$\geq \sum_{i=1}^n I(X_i; \hat{X}_i) \quad \begin{array}{l} X_i \text{ indep: Mut Inf} \\ \text{Independence Bound} \end{array}$$

$$\geq \sum_{i=1}^n R(E d(X_i; \hat{X}_i)) = n \sum_{i=1}^n n^{-1} R(E d(X_i; \hat{X}_i)) \quad \text{definition of } R$$

$$\geq nR\left(n^{-1} \sum_{i=1}^n E d(X_i; \hat{X}_i)\right) = nR(E d(X_{1:n}; \hat{X}_{1:n})) \quad \begin{array}{l} \text{convexity} \\ \text{defn of vector } d( ) \end{array}$$

$$\geq nR(D) \quad \begin{array}{l} \text{original assumption that } E(d) \leq D \\ \text{and } R(D) \text{ monotonically decreasing} \end{array}$$

# Rate Distortion Achievability

---

We want to show that for any  $D$ , we can find an encoder and decoder that compresses  $x_{1:n}$  to  $nR(D)$  bits.

- $\mathbf{p}_X$  is given
- Assume we know the  $p(\hat{x} | x)$  that gives  $I(x; \hat{x}) = R(D)$
- **Random Decoder:** Choose  $2^{nR}$  random  $\hat{x}_i \sim \mathbf{p}_{\hat{x}}$ 
  - There must be at least one code that is as good as the average
- **Encoder:** Use joint typicality to design
  - We show that there is almost always a suitable codeword

First define the typical set we will use, then prove two preliminary results.

# Distortion Typical Set

**Distortion Typical:**  $(x_i, \hat{x}_i) \in \mathcal{X} \times \hat{\mathcal{X}}$  drawn i.i.d.  $\sim p(x, \hat{x})$

$$J_{d,\varepsilon}^{(n)} = \left\{ \mathbf{x}, \hat{\mathbf{x}} \in \mathcal{X}^n \times \hat{\mathcal{X}}^n : \begin{aligned} & \left| -n^{-1} \log p(\mathbf{x}) - H(\mathcal{X}) \right| < \varepsilon, \\ & \left| -n^{-1} \log p(\hat{\mathbf{x}}) - H(\hat{\mathcal{X}}) \right| < \varepsilon, \\ & \left| -n^{-1} \log p(\mathbf{x}, \hat{\mathbf{x}}) - H(\mathcal{X}, \hat{\mathcal{X}}) \right| < \varepsilon \\ & \left| d(\mathbf{x}, \hat{\mathbf{x}}) - E d(\mathcal{X}, \hat{\mathcal{X}}) \right| < \varepsilon \end{aligned} \right\}$$

new condition

**Properties:**

1. Indiv p.d.:  $\mathbf{x}, \hat{\mathbf{x}} \in J_{d,\varepsilon}^{(n)} \Rightarrow \log p(\mathbf{x}, \hat{\mathbf{x}}) = -nH(\mathcal{X}, \hat{\mathcal{X}}) \pm n\varepsilon$
2. Total Prob:  $p(\mathbf{x}, \hat{\mathbf{x}} \in J_{d,\varepsilon}^{(n)}) > 1 - \varepsilon \quad \text{for } n > N_\varepsilon$

weak law of large numbers;  $d(x_i, \hat{x}_i)$  are i.i.d.

# Conditional Probability Bound

---

**Lemma:**  $\mathbf{x}, \hat{\mathbf{x}} \in J_{d,\varepsilon}^{(n)} \Rightarrow p(\hat{\mathbf{x}}) \geq p(\hat{\mathbf{x}} | \mathbf{x}) 2^{-n(I(\mathbf{x}; \hat{\mathbf{x}}) + 3\varepsilon)}$

**Proof:**

$$p(\hat{\mathbf{x}} | \mathbf{x}) = \frac{p(\hat{\mathbf{x}}, \mathbf{x})}{p(\mathbf{x})}$$

$$= p(\hat{\mathbf{x}}) \frac{p(\hat{\mathbf{x}}, \mathbf{x})}{p(\hat{\mathbf{x}})p(\mathbf{x})} \quad \text{take max of top and min of bottom}$$

$$\leq p(\hat{\mathbf{x}}) \frac{2^{-n(H(\mathbf{x}, \hat{\mathbf{x}}) - \varepsilon)}}{2^{-n(H(\mathbf{x}) + \varepsilon)} 2^{-n(H(\hat{\mathbf{x}}) + \varepsilon)}} \quad \text{bounds from def}^n \text{ of } J$$

$$= p(\hat{\mathbf{x}}) 2^{n(I(\mathbf{x}; \hat{\mathbf{x}}) + 3\varepsilon)} \quad \text{def}^n \text{ of } I$$

# Curious but necessary Inequality

---

Lemma:  $u, v \in [0,1], m > 0 \Rightarrow (1-uv)^m \leq 1-u + e^{-vm}$

Proof:  $u=0$ :  $e^{-vm} \geq 0 \Rightarrow (1-0)^m \leq 1-0 + e^{-vm}$

$u=1$ : Define  $f(v) = e^{-v} - 1 + v \Rightarrow f'(v) = 1 - e^{-v}$   
 $f(0) = 0$  and  $f'(v) > 0$  for  $v > 0 \Rightarrow f(v) \geq 0$  for  $v \in [0,1]$

Hence for  $v \in [0,1]$ ,  $0 \leq 1-v \leq e^{-v} \Rightarrow (1-v)^m \leq e^{-vm}$

$0 < u < 1$ : Define  $g_v(u) = (1-uv)^m$

$\Rightarrow g_v''(u) = m(m-1)v^2(1-uv)^{m-2} \geq 0 \Rightarrow g_v(u)$  convex for  $u, v \in [0,1]$

$(1-uv)^m = g_v(u) \leq (1-u)g_v(0) + ug_v(1)$  convexity for  $u, v \in [0,1]$

$= (1-u)1 + u(1-v)^m \leq 1-u + ue^{-vm} \leq 1-u + e^{-vm}$

# Achievability of $R(D)$ : preliminaries

---

- Choose  $D$  and find a  $p(\hat{x} | x)$  such that  $I(X; \hat{X}) = R(D); E d(x, \hat{x}) \leq D$   
Choose  $\delta > 0$  and define  $\mathbf{p}_{\hat{x}} = \{ p(\hat{x}) = \sum_x p(x) p(\hat{x} | x) \}$
- **Decoder:** For each  $w \in 1:2^{nR}$  choose  $g_n(w) = \hat{\mathbf{x}}_w$  drawn i.i.d.  $\sim \mathbf{p}_{\hat{x}}^n$
- **Encoder:**  $f_n(\mathbf{x}) = \min w$  such that  $(\mathbf{x}, \hat{\mathbf{x}}_w) \in J_{d, \varepsilon}^{(n)}$  else 1 if no such  $w$
- **Expected Distortion:**  $\bar{D} = E_{\mathbf{x}, g} d(\mathbf{x}, \hat{\mathbf{x}})$ 
  - over all input vectors  $\mathbf{x}$  and all random decode functions,  $g$
  - for large  $n$  we show  $\bar{D} = D + \delta$  so there must be one good code

# Expected Distortion

---

We can divide the input vectors  $\mathbf{x}$  into two categories:

a) if  $\exists w$  such that  $(\mathbf{x}, \hat{\mathbf{x}}_w) \in J_{d, \varepsilon}^{(n)}$  then  $d(\mathbf{x}, \hat{\mathbf{x}}_w) < D + \varepsilon$

since  $E d(\mathbf{x}, \hat{\mathbf{x}}) \leq D$

b) if no such  $w$  exists we must have  $d(\mathbf{x}, \hat{\mathbf{x}}_w) < d_{\max}$   
since we are assuming that  $d(\cdot)$  is bounded. Suppose  
the probability of this situation is  $P_e$ .

Hence  $\bar{D} = E_{\mathbf{x}, g} d(\mathbf{x}, \hat{\mathbf{x}})$

$$\leq (1 - P_e)(D + \varepsilon) + P_e d_{\max}$$

$$\leq D + \varepsilon + P_e d_{\max}$$

We need to show that the expected value of  $P_e$  is small

# Error Probability

---

Define the set of valid inputs for code  $g$

$$V(g) = \left\{ \mathbf{x} : \exists w \text{ with } (\mathbf{x}, g(w)) \in J_{d,\varepsilon}^{(n)} \right\}$$

We have 
$$P_e = \sum_g p(g) \sum_{\mathbf{x} \notin V(g)} p(\mathbf{x}) = \sum_{\mathbf{x}} p(\mathbf{x}) \sum_{g: \mathbf{x} \notin V(g)} p(g)$$

Define  $K(\mathbf{x}, \hat{\mathbf{x}}) = 1$  if  $(\mathbf{x}, \hat{\mathbf{x}}) \in J_{d,\varepsilon}^{(n)}$  else 0

Prob that a random  $\hat{\mathbf{x}}$  does not match  $\mathbf{x}$  is  $1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}}) K(\mathbf{x}, \hat{\mathbf{x}})$

Prob that an entire code does not match is  $\left( 1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}}) K(\mathbf{x}, \hat{\mathbf{x}}) \right)^{2^{nR}}$

Hence 
$$P_e = \sum_{\mathbf{x}} p(\mathbf{x}) \left( 1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}}) K(\mathbf{x}, \hat{\mathbf{x}}) \right)^{2^{nR}}$$

# Achievability for average code

---

Since  $\mathbf{x}, \hat{\mathbf{x}} \in J_{d,\varepsilon}^{(n)} \Rightarrow p(\hat{\mathbf{x}}) \geq p(\hat{\mathbf{x}} | \mathbf{x}) 2^{-n(I(X;\hat{X})+3\varepsilon)}$

$$\begin{aligned} P_e &= \sum_{\mathbf{x}} p(\mathbf{x}) \left( 1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}}) K(\mathbf{x}, \hat{\mathbf{x}}) \right)^{2^{nR}} \\ &\leq \sum_{\mathbf{x}} p(\mathbf{x}) \left( 1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}} | \mathbf{x}) K(\mathbf{x}, \hat{\mathbf{x}}) 2^{-n(I(X;\hat{X})+3\varepsilon)} \right)^{2^{nR}} \end{aligned}$$

Using  $(1 - uv)^m \leq 1 - u + e^{-vm}$

with  $u = \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}} | \mathbf{x}) K(\mathbf{x}, \hat{\mathbf{x}})$ ;  $v = 2^{-n(I(X;\hat{X})+3\varepsilon)}$ ;  $m = 2^{nR}$

$$\leq \sum_{\mathbf{x}} p(\mathbf{x}) \left( 1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}} | \mathbf{x}) K(\mathbf{x}, \hat{\mathbf{x}}) + \exp\left(-2^{-n(I(X;\hat{X})+3\varepsilon)} 2^{nR}\right) \right)$$

Note :  $0 \leq u, v \leq 1$  as required

# Achievability for average code

---

$$P_e \leq \sum_{\mathbf{x}} p(\mathbf{x}) \left( 1 - \sum_{\hat{\mathbf{x}}} p(\hat{\mathbf{x}} | \mathbf{x}) K(\mathbf{x}, \hat{\mathbf{x}}) + \exp\left(-2^{-n(I(X; \hat{X}) + 3\varepsilon)} 2^{nR}\right) \right)$$

take out terms not involving  $\mathbf{x}$

$$= \left( 1 + \exp\left(-2^{-n(I(X; \hat{X}) + 3\varepsilon)} 2^{nR}\right) \right) - \sum_{\mathbf{x}, \hat{\mathbf{x}}} p(\mathbf{x}) p(\hat{\mathbf{x}} | \mathbf{x}) K(\mathbf{x}, \hat{\mathbf{x}})$$

$$= 1 - \sum_{\mathbf{x}, \hat{\mathbf{x}}} p(\mathbf{x}, \hat{\mathbf{x}}) K(\mathbf{x}, \hat{\mathbf{x}}) + \exp\left(-2^{n(R - I(X; \hat{X}) - 3\varepsilon)}\right)$$

$$= P\{(\mathbf{x}, \hat{\mathbf{x}}) \notin J_{d, \varepsilon}^{(n)}\} + \exp\left(-2^{n(R - I(X; \hat{X}) - 3\varepsilon)}\right)$$

both terms  $\rightarrow 0$  as  $n \rightarrow \infty$  provided  $nR > I(X, \hat{X}) + 3\varepsilon$

$$\xrightarrow{n \rightarrow \infty} 0$$

Hence  $\forall \delta > 0$ ,  $\bar{D} = E_{\mathbf{x}, g} d(\mathbf{x}, \hat{\mathbf{x}})$  can be made  $\leq D + \delta$

# Achievability

Since  $\forall \delta > 0$ ,  $\overline{D} = E_{\mathbf{x},g} d(\mathbf{x}, \hat{\mathbf{x}})$  can be made  $\leq D + \delta$   
 there must be at least one  $g$  with  $E_{\mathbf{x}} d(\mathbf{x}, \hat{\mathbf{x}}) \leq D + \delta$

Hence  $(R,D)$  is achievable for any  $R > R(D)$

that is  $\lim_{n \rightarrow \infty} E_{X_{1:n}} (\mathbf{x}, \hat{\mathbf{x}}) \leq D$

In fact a stronger result is true:

$\forall \delta > 0, D$  and  $R > R(D)$ ,  $\exists f_n, g_n$  with  $p(d(\mathbf{x}, \hat{\mathbf{x}}) \leq D + \delta) \xrightarrow{n \rightarrow \infty} 1$

- **Huffman:** Bottom-up design. Optimal.  $L_H \leq H_D(x) + 1$ 
  - Designing with wrong probabilities,  $\mathbf{q} \Rightarrow$  penalty of  $D(\mathbf{p}||\mathbf{q})$
  - Long blocks disperse the 1-bit overhead
- **Arithmetic Coding:**

$$C(x^N) = \sum_{x_i^N < x^N} p(x_i^N)$$
  - Long blocks reduce 2-bit overhead
  - Efficient algorithm without calculating all possible probabilities
  - Can have adaptive probabilities

# Summary (5)

---

- Typical Set

- Individual Prob  $\mathbf{x} \in T_\varepsilon^{(n)} \Rightarrow \log p(\mathbf{x}) = -nH(X) \pm n\varepsilon$
- Total Prob  $p(\mathbf{x} \in T_\varepsilon^{(n)}) > 1 - \varepsilon$  for  $n > N_\varepsilon$
- Size  $(1 - \varepsilon)2^{n(H(X) - \varepsilon)} < |T_\varepsilon^{(n)}| \leq 2^{n(H(X) + \varepsilon)}$
- No other high probability set can be much smaller

- Asymptotic Equipartition Principle

- Almost all event sequences are equally surprising

# Summary (6)

---

- DMC Channel Capacity:  $C = \max_{\mathbf{p}_x} I(X; Y)$
- Coding Theorem
  - Can achieve capacity: random codewords, joint typical decoding
  - Cannot beat capacity: Fano
- Feedback doesn't increase capacity but simplifies coder
- Joint Source-Channel Coding doesn't increase capacity

# Summary (7)

---

- **Differential Entropy:**  $h(x) = E - \log f_x(x)$ 
  - Not necessarily positive
  - $h(x+a) = h(x)$ ,  $h(ax) = h(x) + \log|a|$ ,  $h(x|y) \leq h(x)$
  - $I(x; y) = h(x) + h(y) - h(x, y) \geq 0$ ,  $D(f||g) = E \log(f/g) \geq 0$
- **Bounds:**
  - **Finite range:** Uniform distribution has max:  $h(x) = \log(b-a)$
  - **Fixed Covariance:** Gaussian has max:  $h(x) = \frac{1}{2} \log((2\pi e)^n |K|)$
- **Gaussian Channel**
  - **Discrete Time:**  $C = \frac{1}{2} \log(1 + PN^{-1})$
  - **Bandlimited:**  $C = W \log(1 + PN_0^{-1} W^{-1})$ 
    - For constant C:  $E_b N_0^{-1} = PC^{-1} N_0^{-1} = (W/C) \left( 2^{(W/C)^{-1}} - 1 \right) \xrightarrow{W \rightarrow \infty} \ln 2 = -1.6 \text{ dB}$
  - **Feedback:** Adds at most  $\frac{1}{2}$  bit for coloured noise

# Summary (8)

---

- **Parallel Gaussian Channels:** Total power constraint  $\sum P_i = P$ 
  - **White noise:** Waterfilling:  $P_i = \max(P_0 - N_i, 0)$
  - **Correlated noise:** Waterfill on noise eigenvectors
- **Rate Distortion:**  $R(D) = \min_{\mathbf{p}_{\hat{X}|X} \text{ s.t. } Ed(X, \hat{X}) \leq D} I(X; \hat{X})$ 
  - **Bernoulli Source** with Hamming  $d$ :  $R(D) = \max(H(\mathbf{p}_X) - H(D), 0)$
  - **Gaussian Source** with mean square  $d$ :  $R(D) = \max(\frac{1}{2} \log(\sigma^2 D^{-1}), 0)$
  - **Can encode at rate R:** random decoder, joint typical encoder
  - **Can't encode below rate R:** independence bound
- **Lloyd Algorithm:** iterative optimal vector quantization
